> no radiation]

The line will have minimum or no radiation only if fed at the transmitter end with a balanced feed. An unbalanced feed will create unequal currents in the conductors, resulting in radiation. A symmetrical (e.g., twinlead) line doesn't assure balance (equal and opposite currents in the two conductors), and an unbalanced line will radiate, regardless of its physical construction.

> A balanced antenna fed with balanced line, and the line goes away from
> the antenna non-perpendicular [other than 90 degrees angle] for a
> minimum of 1/4 wavelength is an improperly installed antenna system:
> [line will radiate]

True for both symmetrical line and coax. Radiation is due to common mode current induced on the line. It can be reduced by inserting "current baluns" (common mode chokes) in the line. A couple spaced about a quarter wavelength apart are usually adequate.

> A balanced antenna fed with un-balanced line, and the line goes away
> from the antenna perpendicular [90 degrees angle] for a minimum of 1/4
> wavelength is an improperly installed antenna system: [line will radiate]

The amount of common mode current and therefore radiation depends on the length of the path along the outside of the coax to ground. A current balun (common mode choke) at the feedpoint will reduce the current and therefore radiation.

> A balanced antenna fed with un-balanced line, and the line goes away
> from the antenna non-perpendicular [other than 90 degrees angle] for a
> minimum of 1/4 wavelength is an improperly installed antenna system:
> [line will radiate]

This is due to induced common mode current. The mechanism is identical to that when a symmetrical line is used.

> A balanced antenna fed with un-balanced line and a properly installed
> balun, and the line goes away from the antenna perpendicular [90 degrees
> angle] for a minimum of 1/4 wavelength is a properly installed antenna
> system: [line has minimum or no radiation].

Correct. A current balun at the feedpoint reduces the conducted common mode current. Induced common mode current is prevented by symmetrical feedline placement.

> An un-balanced antenna fed with balanced line is an improperly installed
> antenna and the line will radiate.

Coax feeding an unbalanced antenna will radiate just as much as twinlead feeding an unbalanced antenna.
>
> NEED I CONTINUE??

A lot of people have learned a list of handy rules like this without having much of an understanding of where they came from or under what circumstances they do and don't apply. For anyone interested in learning more about common mode current, feedline radiation, types of feedlines, and feedline radiation, I suggest taking a look at http://eznec.com/Amateur/Articles/Baluns.pdf. It deals only with conducted common mode current and doesn't discuss induced common mode current -- I'll try to get together a supplement covering that topic when I have time. There was some discussion on this newsgroup not long ago about induced common mode current, but I can't locate the topic right off. It should be possible to find it with a google search. Be sure to also look at the work by Walt Maxwell, W2DU referenced at the end of the balun article.

Scotty -

The first step I would take is get replacement stainless steel hardware - IF this was version before that usage.

These web pages may be helpful
http://www.iol.ie/~bravo/Troubleshooting%20Traps.htm

If you try to disassemble the driven element traps on the Cushcraft A3 - the proper way to remove the trap covers is to slip the black trap caps off. If the traps have been up in the weather for a while, it may be difficult to remove them without breaking them.
You can order replacement caps from Cushcraft. they were around $1.30 apiece in 2001. There are 24 caps on an A3S.

When your A3 was new, the traps had a paper sticker indicating which was which. Why the traps weren't engraved or marked with a permanent sticker is a mystery that only CC can answer. Taking them apart though is not one of them though! Inside - the traps look the same.

1) Attach them using very short leads to a HP network analyzer and punch up the Smith chart. Start around 18 Mhz , and crank the frequency up until the readout on the display switches from inductance to capacitance. Note that
frequency. You will find 2 whose frequency is about 150Kz higher than the other 4.

2) Use a grid dip meter placed end to end on a non-conductive table to determine which 2 resonate higher that the other 4. The network analyzer is a better approach.

Cushcraft directions (via email on towertalk / contesting.com) for trap disassembly:

The traps of the A3 and A3S can only be separated one way.
First of all, the 10 meter traps are the same and you can use them in any position. Be sure the end with the contact screw for the body to element junction is
nearest the boom.
The 15 meter traps can be identified by the fact that they are "swagged" to a smaller tubing size on the outboard side. There are 2 different types of 15 meter traps. 4 of the traps are used in the reflector and driver elements. There are two 15 meter traps that are used in the director and they have a higher frequency of resonance. That is the only way to tell the difference. Check the traps with a dip meter and that should tell you which are which."

Cushcraft used to perform this service often for a nominal fee, but it looks like that level of support has stopped.

Sounds like you simply need to contact your credit card company with a copy of the original quote and have them credit you with the difference. They should be willing to take care of this without any problem; at least that's been my experience.

Good luck
Fred

Walt,

I reported a model at the following link:

http://www.smeter.net/feeding/feedpowr.php

At resonance it reports a 'normal' pattern. Off resonance it reports up to 90% feedline radiation. I intend to mimic the results this weekend. I will build a 10 meter dipole, misfeed it, an measure the results. I will let you know.

Richard

I suspect that you have confused yourself about the distance and elevation angle to satellites. I'm sure you can clear up the situation if you consider the distance to the geostationary satellite 22,300 miles above the equator when it is viewed from somewhere near the North or South Pole.

Try "misfeeding" a 10m dipole with N*1/2WL 450 ohm ladder-line
through a good choke and get back to us. (N is a natural number)

They are still on here in San Antonio. I no longer recall exactly where their transmitter is located, and haven't
taken time to look it up on one of the look up sites. The one I used to use and have stored in my favorites is gone,
and I haven't replaced it. Do you have the transmitter location? I *think* it is somewhere in Jefferson Parish.

Use a mag-mount. Route the coax out the bottom of the side window.
You don't have to drill. A piece of saran wrap protects the paint.
A friend I know used a stick-on-the-glass antenna to make the xyl happy.
He had trouble with the swr swinging all over the place.
I forget the brand he used.

Read Genesis 6. We get only heavily edited, redacted bits and pieces
of old myths. Much has been thrown out, edited out, gone
forever.
We just a few bits of the old myth peeking out through cracks in the
old testament.

Where did they come from? What was the deal with them? Well
that has been edited out and we wil never know, except
the fossil language. Behold the man has become one of us to know
good and evil... Why the magic fruit trees? There is a lot
that was taken out of the original myths.

==========

Walt,

If you erect a 10 meter 1/2-wave dipole and center-feed it with a 50 feet length of coax, and then transmit on 1.9 MHz, 99.9 percent of available power will be radiated from the feedline and only 0.1 percent from the antenna itself.

SWR on the line will be about 1400 and the amount of power available will not be very great.

Reg.

Source record: 71215

If anyone besides me is having trouble keeping track of what Reg is trying to say, maybe the following recent quotes will help. That is, they'll help you understand why you're having trouble keeping track.

For what it's worth, I agree with the first quotation of 8/31. But apparently Reg doesn't, even though he said it.

Roy Lewallen, W7EL

8/30:

Perhaps somebody might be prepared to state the power actually radiated from feedlines in watts. At least it may create the impression you know what you are talking about.

8/30:

Roy, do everybody a favour, by stating, numerically, how much power is radiated from feedlines. Then somebody might have some confidence in what you are bafflegabbing about.

8/31:

Any current which finds its way on to (3), which ought to flow in the antenna, will result in the coax participating in the radiation pattern of the whole antenna structure.

BUT IT IS A SILLY QUESTION TO ASK HOW MANY WATTS ARE RADIATED FROM THE FEEDLINE.

OR, CONVERSELY, HOW MANY MICROWATTS ARE PICKED UP BY THE FEEDLINE ON RECEIVE.

The feedline cannot be treated in isolation as if it behaves independently of the antenna. For starters, the radiation resistances of the feedline and antenna do not add arithmetically. They interact with each other.

8/31:

If you erect a 10 meter 1/2-wave dipole and center-feed it with a 50 feet length of coax, and then transmit on 1.9 MHz, 99.9 percent of available power will be radiated from the feedline and only 0.1 percent from the antenna itself.

http://www.smeter.net/feeding/feedpowr.php:

Centre-Fed Dipole - Radiation from Coaxial Feedline
Author: R.J.Edwards G4FGQ ï¿½ 25th March 2003

Program Notes
. . .
With no loss in accuracy, to simplify the model, the transmitter is
located at the dipole centre and the coaxial line is replaced by a
single conductor of the same diameter as the coaxial braid. There are 3
radiating elements. Radiation resistance, input impedance, and input
current of each element is calculated. Finally, the percent of total
power radiated by each of the three elements is calculated.

I think most RF people would consider radiant heat from the feedline
to be heat dissipation (as opposed to RF radiation).

The following are my findings on an IC751, which I had previously posted on another NG:
"As an example; the Icom IC-751 S meter calibration procedure requires that the S meter adjustment pot be set to S9 +40dB, with 5 mV at the antenna input. The S meter should then be verified to show: S8 - S9 with 50 uV input, and S2 - S3 with 5 uV input. Note that this approximates to 3.33dB per S unit. The amateur standard has traditionally been 6 dB per S unit.

I have calibrated my IC-751 as per the manual instructions. 50 uV reads S9 + 15 dB, and 5uV reads S5. Increasing the generator above 5uV requires 11 dB to reach S9, or 2.75 dB per S unit."

I have seen it claimed that linear amplifiers often provide more than the theoretical gain, and that the cause is some indefinable ionospheric nonlinearity rather than meaningless S meters!

Regards,

Frank

Roy, W7EL wrote:
"The calculations you qupte assume equal and opposite (i.e. purely differential mode) currents in the feedline conductors. The topic under discussion is radiation due to common mode current."

Radiation from current on the outside of a coax feedline can be calculated too by using formulas appropriate to the actual current distribution.

Refer to the infamous "ARRL Antenna Book" figure (Fig 24 on page 26-16 of my 19th edition), "showing various current paths at feed point of a balanced dipole fed eith unbalanced coaxial cable."

From the text:

"The antenna current in arm 2 is thus equal to the difference between I2 and I3.

The magnitude of I3 (on coax exterior) is proportional to the relative impedance in each current path beyond the split."

Best regards, Richard Harrison, KB5WZI

We should not confuse more than advertized gain with more than advertized output, though. A 1KW amplifier could quite likely have 1KW output with 70W in. That does not mean 1.2KW linear output with 120W in. Still, the extra gain is useful; some claimed 100W radios will not put out 100W on all bands.

A ground rod would result in rather high ground losses.
With woods all around, why not put up a multi-band dipole?

I know the feeling Fred. I was trying to work a new SA station on 17m the other night with my measly 100w to an R7. Time after time I would hear the DX station say.."nice to work you again ________", one guy he even commented on working about 6 times over the last year. Well I finally worked him for the new one, only to find I had already worked him on 20m 14 years ago. At least it wasn't on the same band!

I am a DEC with ARES and have been told by a number of newer hams that ARES is obsolete in the 21st Century.

It was pointed out to me that echo link, cell phones, wireless internet etc etc. obviated the need for a "bunch of old farts" that couldn't read the handwritting on the wall...

We all watched in amazement as New Orleans was relagated to the Stone Age. All the wizz bang technology fell on it's hind parts. No cell phones, no internet, no echo link, no communications.

No emergency system that relies on intact infrastructure can be relied upon period! Those who fail to heed this lesson, are doomed to repeat it.

Now take it one step further and change the disaster to a nuclear explosion. The EMP wipes out all the rest of the neat toys necessary to communicate in the digital modes.

The SOS and requests for help being transmitted on CW from an old tube type rig go unanswered, as no one can understand code. Mores the pity.

That was my first choice. I am not strong on antenna theory, so I and afraid to
build one. I was looking at a Alpha Delta DX-CC, but they have been on backorder
sonce March. I emailed them 3 weeks ago, and they said 7-10 days. I emailed them
again today, and they said 2 weeks. I liked that antenna because of the coax
feed. I was trying to sta away from the other dipole that use ladder line.

A 130 ft. dipole fed with 450 ohm ladder-line through a good
choke is hard to beat as an all-HF-band antenna and costs
about $25.

I will agree that it is best to go with a beter antenna, sometimes it is just not practical. Not many can put up a beam for 80 meters and not that many for ever 40 meters. Most amps will do 80 to 15 meters. Some will go to 10 meters. The specs for a TH3 tribander is only 5.8 db over a dipole. That is slightly less than 4 times the power. That is only for 20,15, 10 meters. That only takes your 100 watt rig to 400 watts. An amp that is worth buying will put out atleast 600 to 800 watts and you can almost double that and stay legal.

If you have to pay someone to put your beam antenna, the cost will go way over the $ 1400.

The thing of hearing a station and he can hear you is also bogus in some cases. I was trying to work a mobile on 80 meters that was parked running 100 watts. I could hear him just fine. About 1/4 scale on my S-meter. He could not hear me for some local (to him) qrm and qrn. By turning on my amp we could work each other.

The amp will not let you turn it to cut out some qrm/qrn like the beam may.

Hustler 5BTV popular here and used at about 4 1/2 inches off the ground
without radials.
May have to do with pretty good soil conductivity here in south central
Oklahoma. Our local Elmer tells us ground moisture hasn't much to do with
effective antennas. Quien Sabe?

As an alternative to a trap vertical, you might consider a horizontal
trap dipole.

Probably cheaper than the Hustler and a pretty good performer if the
trees in the woods are high enough (at least 30 feet).

They come in different lengths based, in part, on the lowest design
frequency.

No radials or tuner required. Ultra simple.

The idea that if you can hear a station he can hear you is totally wrong, especially at HF. At HF, you can have a terribly inefficient antenna and hear people just fine. This is because the dominant noise is coming from outside the receiver and therefore both signal and noise are attenuated by the same amount by the loss. I can easily hear 20 meter DX on my little Sony SW radio with a 2 foot rod antenna. But there's no hope they'd hear me if I were transmitting with that antenna, even if I'm running an equal or much greater amount of power than they are.

At VHF and above, where receiver noise dominates, a station you hear can hear you if you're running about the same amount of power and if your receivers have about the same noise figure. But this isn't at all true at HF and below.

My experience was with a 4BTV that was mounted about 15' above ground
with several sets of (nominally) resonant radials. This was better
than a dummy load, but not much.

I second the idea of one or more dipoles in the trees. Without a
decent ground -and- being in the trees, the vertical will be a very
big disappointment I'm afraid.

I don't see the appeal of one antenna that is capable of being matched
on every band, when the radiation is poor. The Alpha-Delta DX-CC
leaps to mind.

Pick two or three bands and get your feet wet. The higher bands are
poor these days anyway. I would put up a dipole for 20 and one for
80. These can be fed in parallel without interaction if place at
right angles to each other. You will have a daytime band and a
nighttime band and you will make contacts.

What do you have to lose or fear? You need the coax and balun anyway
and a few bucks worth of wire and you're in business.

Do any of you ever think that the DX stations just might get tired of
giving out 59s (or 33s in you guys cases) and might actually want to
engage in some civilized conversation with someone they've worked over
and over?

If a big antenna and higher power make this more enjoyable, what's the
issue? Oh, I almost forgot, this is the land of welfare and
entitlements.

Come on Roy, your picking an example that has nothing to do with the real world. How many people try to work 20 meters on a 2 foot Sony whip?

I failed to state the obvious. Given: Both stations are using antennas matched to the transmitter and of a length appropriate to the band being utilized. YaDa YaDa.

Back in the AM days, my wife heard me coming out of a skillet on the stove. I doubt she could have talked back to me no matter how high she turned up the heat. :>)

I have to do a inverted V config. I would be unable to run it horizontal. Can I
build one using simply a coax feed?

>I have to do a inverted V config. I would be unable to run it horizontal. Can I
>build one using simply a coax feed?

A single dipole, fed with coax, configured as an inverted V, will
serve well on its resonant frequency and is also usable on its odd
harmonics. For example, a dipole cut for 40 meters (nominally 66 feet
in length for a horizontal, and perhaps 60 feet in length as an
inverted V) can usually be used on 15 meters as well since that's
close to the third harmonic.

Such an antenna will not serve well as an "all-band" antenna. Its
feedpoint impedance will be too high, or too reactive, on non-resonant
bands (e.g. on 20, the above dipole will have a very high feedpoint
impedance). You may be able to tune it on non-resonant bands using a
wide-range external transmatch, but the losses in the coax and
transmatch due to the high VSWR will likely be prohibitive.

Several solutions to this:

- Feed the dipole with ladder line or open-wire line, use a good choke
or balun and a good tuner/transmatch, and if necessary tune the
length of the wire so that the impedance seen at the transmatch is
acceptable.

- Build a multi-wire "fan" dipole, with one set of wires cut for each
band of interest. These are somewhat easier to trim (less
interaction between the wires) if the wires are fanned apart at a
broad angle, but it's quite possible to get them to work with each
wire simply hanging 6" below the next-longest one using simple
insulators of some sort. I use a three-wire fan dipole of this
sort, cut for 40/20/10, fed with coax, and it works quite respectably.

- Use a trap dipole (feeding with coax should be fine).

However, although it may "match" on 15-meters it will not work all
that great as the effective antenna height will be substantiality
lower. (Been there done that!).

Can I use inulated 14 AWG wire and not use the fan method? Can I run them tied
together?

>- Use a trap dipole (feeding with coax should be fine).

==========
Walt,

Back along the thread you asked for details of the experiment which demonstrated that a feedline could radiate as much as 90 percent (of the available power). But you received no reply.

So I provided an example in which nearly all the power is radiated by the feedline simply because the short antenna is unable to accept very much and is inefficient. The power available at the antenna input HAS to go somewhere if it cannot be accepted by the antenna.

Walt, my statement is correct. There is NO choke balun involved. The unbalanced coax goes straight into the balanced antenna which inevitable injects power into the outside of the coax. The choke is omitted just to acheive that purpose.

I made the statement because you seemed to doubt it was possible for 90 percent of the available power ever to be radiated from an unbalanced feedline. I may possibly have mis-interpretted you.

Admitted, there may not be very much power available at the antenna due to high SWR and loss within the coax. But nevertheless most of the power will be radiated by the outside of the feedline. The feedline makes an excellent, efficient antenna wire compared with the dipole.

An approximate analysis can possibly be done by using Eznec and placing the transmitter directly at the center of the dipole.

The outer conductor of the coax can be represented by a thick wire down to ground, the transmission loss inside the coax being ignored without having the slightest effect on the experiment.

Incidentally, the length of the feedline in wavelengths and the resistance of the bottom end ground connection will have a considerable effect on results.

I mention Eznec because of the number of people who swear by it.

For Roy's benefit, the experiment will not tell him how many watts are radiated from the feedline because it is impossible to separate the three radiation resistances involved and there will be only one very peculiar radiation pattern from their combination.

I entered this extremely long-standing discussion only to say that, in general, the amount of "Power Radiated from a Feedline" is not worth the effort which has been expended in waffling about it.

I use the words "Power Radiated from a Feedline" only because, to make myself understood, I am obliged to use the same confusing language as used by old-wives for the last 50 years. I try to be helpful.

The closer the wires are together, the greater the amount of
electrical coupling between them. As the amount of coupling
increases, the wires' ability to behave independently decreases... one
effect is that the useful SWR bandwidth of the wires becomes narrower.
The presence or absence of insulation won't have too much effect on
this change... some, but not a lot.

Eventually, if the wires are close enough together, they'll tend to
behave pretty much like one wire (the longest one) which is "fatter"
near the feedpoint, and you'll lose the ability to tune the
higher-frequency bands properly.

A separation of 4-5" inches seems to work pretty well. There are
plans in one of the ARRL handbooks which show a "fan" dipole made from
300-ohm twinlead, with one wire cut off short (and a second 300-ohm
section with two even shorter wires hung an inch or so below). I'd
expect this to have a narrower useful bandwidth on the shorter-wire
bands than one with a 4" separation.

I've even heard of people making these sort of fan dipoles out of
computer-type ribbon cable, in which the wires are only about a tenth
of an inch apart! I have no personal experience with this particular
version and don't how well this actually works in practice, but I have
a feeling it might be difficult to get to tune properly.

I suppose you could try making one with insulated wire, with the wires
tied together every few feet, and the shorter (lower) wires being tied
in loosely so that they sag downwards a few inches in between the
ties. This might separate 'em enough to allow for independent tuning.

If you can use insulators, do so, is my advice. You can make
insulators very cheaply from short lengths of 1/2" PVC irrigation
tubing.

A similar set of examples of apparent one way HF communication:
Michigan to Bangladesh in the rainy season. [much more QRN at one end than the other]
Michigan to Antarctica in the (N.A.) Summer [heavy QRN on one end, none on the other end]

... and then there are the paths that have to go through the magnetic pole ...

These examples assume reasonable equipment in a rural setting.

If you go with coax, you probably should use multiple dipoles (fan)
or a trapped dipole to obtain a low feedpoint impedance on your
bands of choice.

But how much of that power is heat and how much is RF?
With an SWR of 1000:1, the I^2*R losses are bound to
be pretty high.

Sorry to disagree, Reg, But if a balun at the feedline-antenna
junction is a perfect balun at 1.9 MHz, NO power will be radiated from
the feedline with any amount of SWR, even 1400. It is true that only
0.1% of the power will be radiated, but the 99.9% will be reflected
back to the input of the line, not radiated,, making a 50-ohm
transmitter see a 1400:1 mismatch. In the steady state the transmitter
will only deliver 0.1% of its available power into the line due to the
mismatch.

The 1400 SWR inside the coax will not cause it to radiate, unless the
outer conductor is full of holes.

Walt

==========

Your question is not relevant. We are concerned only with the possible high ratio of feedline radiation to radiation from the antenna.

If you are worried about transmission loss in the coax then that can be reduced by transmitting at a higher frequency than 1.9 MHz where the 10m dipole provides a better terminating impedance and SWR will be lower.

With an appropriate line-length in wavelengths the coax can still be forced into radiating better than the short 10m dipole.

But the conditions under which this occurs are NEVER those under which the system would normally be operated.

Under normal conditions, eg., transmitting on 29 MHz, radiation from the feedline is low enough never to cause interference to the neighbor's television. If such an unwelcome event should occur then it will be due to legitimate high-power radiation from the dipole and your conscience will be clear.

Now Cecil, you can stop trying to pull my leg. ;o)

Reg.

Thank you for the detailed explanation, Reg, I'm sorry I began
transmission while off frequency. I jumped on too soon without
considering you were talking specifically a condition without a balun.
You are correct about the feedline radiation without the balun.
However, with the 1400 SWR in the case you described, because even
though the SWR at the input of the feedline will be substantially less
that at the load, the mismatch seen by the source will allow only an
insignificant amount of the available power to be delivered to the
feedline.

Walt

I'm just wondering how 99.9% of the power can be radiated
from the feedline when 80% of the power turns to heat in
the feedline. Is that what is known as gain? :-)

72. EMRP effective monopole radiated power

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-02 13:44:29 UTC
From: CD <mr.whatever@gmail.com>
Message-ID: <1125668669.498531.146570@g44g2000cwa.googlegroups.com>
Source record: 71169

Hello again everyone,

I was reading through a transmitter datasheet and it stated that it is capable of outputting 1-50W. However, I got an email from the company stating that it is only designed to work at 1W EMRP. Upon further reading, I discovered that the effective monopole radiated power is the transmitter output power multiplied by the antenna gain.

I'm a bit confused because if EMRP depends on antenna gain, then can't the antenna be designed to have a higher gain and thus have a higher EMRP? How can a transmitter be designed only for 1W EMRP? Does changing the antenna design likely affect the transmitter performance?

I figured since the TX has a standard 50ohm output impedance, then as long as I match the antenna I should not worry about VSWR going over the max rating for the TX, no?

Thanks!

Your challenge is rather silly and infantile.

Perhaps it is indicative of the malaise that
prepossesses Yankland when Yankland visits the
same style of destruction on the innocent
citizenry of the World?

You did not help me during WWII.

I am not showing "utter disregard for the suffering
of the people". Far from it, but your self-obsession
and the self-obsession of Yankland might lead you
to think so.

Reg Edwards wrote:
> Now Cecil, you can stop trying to pull my leg. ;o)

I'm actually trying to make a technical point, Reg.
Walt may be trying to make that same technical point.
The SWR is based on differential energy which doesn't
radiate from the feedline. It just seems to me that
you are trying to have your reflected power and radiate
it too. That doesn't work for radiated power any better
than it works for cake. If the SWR is 1400:1 then the
reflected power is almost equal to the forward power both
of which are associated with *differential* currents which
don't radiate.

If the SWR on the feedline is 1400:1, almost no power
is being radiated! The forward power is 100 watts
then the reflected power is 99.7 watts. Both of these
powers are based on *differential* currents and therefore
don't radiate from the feedline. There's only 0.3 watts
available to radiate.

If 99.9% of the power is being radiated by the outside
braid of the coax, then the reflected power cannot be
more than 0.1% of the power and as a result of that
fact, the SWR on the feedline must necessarily be
very low, i.e. close to 1:1. Seems to me you need to
resolve that contradiction.

You cannot radiate 99.9% your reflected power and still
have it available to the SWR measuring equipment. If the
reflected power is available to the SWR measuring equipment,
it is composed of *differential* currents and is, by definition,
not radiating. If it is radiating, then it is not available to
the SWR measuring equipment and the SWR is, therefore, low. You
simply cannot have a sky high SWR on the feedline with the
feedline radiating 99% of the power. The SWR meter cannot tell
if the antenna or coax braid is doing the radiating and will
report a very low SWR.

I had occasion to replace a 150 foot run of wire to a well a year or so
back. After discovering how shallow the original wiring had been planted, I
was able to duplicate the
run burial by using a sharpshooter spade, it took less than two hours. I
just pushed the spade into the ground and levered open a shallow slot. That
worktime included protecting the new wiring with PVC pipe where it ran
across a pair of gravel trailer parking pads. I realize a really effective
radial system would probably involve more wire than that, but you'd probably
want to do it in short work sessions anyway.

A good point.

WWII was started by Britland with the express purpose
of dispersing the invaders from Poland, and yet the
war ended with invaders in Poland.

Therefore, Britland (and Yankland for all its pompous
posturing) _LOST_ WWII.

Normally a transmitter is rated to provide some value of r-f power output into a load having no more than 'X:1' SWR with respect to the load impedance the tx is designed for. Such a load can be provided by a large number of antennas of different directional gains, yielding different ERPs even though the tx output power into each antenna type is the same.

One possible concern of the tx manufacturer for ERP might be related to how well his product is shielded. But such a concern probably indicates a rather inferior design.

>>> http://www.smeter.net/feeding/feedpowr.php

We are in a position now to say what is wrong with that program.
Essentially, it violates the conservation of energy principle.

Energy cannot exist as both reflected power and radiated power
at the same time.

If the SWR is 1400:1, the feedline cannot be radiating much
because the reflected power is 99.7% of the forward power
and both are based on differential currents which don't
radiate. That leaves only 0.3% of the power available for
radiating by the feedline.

If 99.9% of the power is radiated by the coax braid, then the
feedline SWR must be very close to 1.6:1 because the ratio of
reflected power to forward power can be no more than 0.1/100.

As with cake, you cannot have your reflected power and radiate
it too. Reflected power plus radiated power cannot add up to
more than the forward power. In fact, Pfor = Pref + Prad
If 50% of the power is radiated by the antenna plus feedline,
then 50% of the power is reflected and the SWR is 5.83:1.

You're saying the Brits started WWII? Are you trying to rewrite
history?

What do you believe Hitler's German troops were doing in the
Sudetenland in 1938, rounding up rebels?

What were Hitler's V-2 rockets doing over London, cleaning out their
chimneys?

Your railing against the US is hurtful, and shows how demented you
are.

... and therefore incapable of melting down the inner conductor of the coax, and/or causing catastrophic failure of components in the output network of the tx PA.

But, given enough tx power, these failure events are common when a tx tries to supply its full output power into a very high mismatch at the end of a run of coax. I have had to fix some of these systems after this happened to them.

Please explain how this fits with your theory, Reg.

> SNIPPED

It s easy to see you have no concept of how things work. An 8 foot whip is about as big as most mobiles can use. I just worked a friend of mine that does a lot of camping. He uses either a screwdriver antenna or a dipole only up about 10 to 15 feet depending on where he is at. Most distances are around 200 miles from my house. There does not seem to be much differance in his signal with that low dipole. I am sure the dipole would be beter if he could get it up higher, but you use what you have.

Many times the absolute strength of the signal does not make that much differance. It is how well you can get above the noise and qrm that is on the bands. That is where the beter antenna and higher power come in.

All of this is for the low bands , when you get to vhf and above then the antenna system usually becomes all important.

I'm guessing that you aren't a ham or that if you are this transmitter
is specified for some other service that is regulated to 1 W erp.
With an efficient antenna the transmitter output should be limited;
with a less efficient antenna the transmitter has reserve capability
to overcome the inefficiency.

Just a guess...

Bear in mind that current flowing in a conductor will always generate a
field. Alternating current flowing in a (straight) conductor will
always generate a radiating electromagnetic field. That radiating field
will convey energy if it is not nulled by another equal and opposite
field. You need to demonstrate that all the fields resulting from all

the currents are nulled in this scenario.

Back into the woodwork.

Source record: 71090

I'm not sure where in this convoluted thread to put this, and please excuse me if the point has been made before but I just wanted to reiterate...

When you put up an antenna system, pretty much _everything_ in the vicinity of the wires you think of as the "antenna" is actually part of the antenna system. Of special concern are all conductors, as well as big pieces of dielectric material and lossy material. Certainly ground has a profound effect on the radiation pattern, for example.

I'm really not so concerned with "how much power is radiated from my feedline" as I am with "what is the radiation pattern (and in some cases, efficiency) of my entire antenna system." To the end of controlling the radiation pattern, I may wish to suppress antenna currents on things like support wires and feedlines. Or, I may model the system and find that antenna currents on the feedline are really not a problem. In the case where I do care, I can add "current baluns" or "choke baluns" or other structures as needed, or change the configuration to break up the unwanted currents. In some cases, a balun can be as simple as a hunk of ferrite clamped over the feedline. I've also used self-resonant coils of coaxial feedline to very effectively suppress current at a particular frequency. Breaking up support wires with insulators can be very useful.

If you think that antenna current on the feedline is always a BAD thing, consider the coaxial collinear, where the sections of feedline that compose the antenna are INTENDED to radiate. On the other hand, with that antenna, it's very important to suppress antenna current on the line feeding the antenna part, because it doesn't take much antenna current on that line to mess up the radiation pattern. But with an 80 meter coax-fed dipole, the pattern may actually be better for some purposes if you don't suppress the antenna current on the feedline.

Again, the question I care about is, "What is the pattern for this antenna," not "How much power does the feedline radiate." Is this really so different from caring more about properly loading a transmitter and getting power efficiently to the antenna, instead of caring specifically about transmission line SWR? Focus on what gets you the results you want, not on red herrings or old husband's tales.

Cheers,
Tom

It is true by definition for ideal coaxial feedlines in which the
radiating fields are 100% nulled by the basic shielded design, i.e.
solid copper outer tubing much thicker than the skin effect depth.
The problem with the program is that the conclusions violate the
conservation of energy principle. It is simply impossible to have
a coax SWR of 1400:1 while radiating 99.9% of the power from the
feedline.

I guess the word is "Kool!"
our Wal-Mart ran out of nitrogen toilets, so nitrogen flushing may be a
second alternative.

>
You can make the boom out of anything that will be mechanically strong enough. If it is conductive or not will have an effect on the lengths of the elements. It will also change if the elements are insulated or not. Depending on the design of the driven element element, it may or may not be connected to the boom.

You really need to just find the type of beam you want and copy it. If you find one you want and the frequency is diffeant , you can scale it, but you must be sure to scale all the parts, boom diameter, element diameter and all the other elements.

Walter, W2DU wrote:
"What became WWII was without question the Hitlerian invasion of the Sudetenland."

Maybe so, but it was taken without firing a shot.

I recall that on September 29, 1938, Neville Chamberlin, Adolph Hitler, Edouard Daladier, and Benito Mussolini signed the Munich Agreement which transferred to Germany the Sudetenland, that contained a large German-speaking population from Czechoslovakia.

Chamberlin, caricatured in the U.S. with his umbrella and briefcase, shared with Hitler an extreme dislike of bolsheviks. These proclivities were demonstrated during the 1937 Spanish Civil War.

Chamberlin, the appeaser, went home from Munich declaring "Peace in Our Time".

On September 1, 1939, nine days after signing a nonagression pact with the Soviet Union, in the predawn darkness, Hitler attacked by land, sea, and air, and captured by day`s end, the Polish port city of Danzig.

WW-2 officially began two days later, on September 3, 1939 when Brittain and France declared war on Germany.

Best regards, Richard Harrison, KB5WZI

110. 80m Inverted L Initial measurements

45' high, 25.8 sloping wire at the top, 29 feet high at the far end. #12 THHN Insulated copper wire, stranded.

Predicted Radiation Resistance: 25.8 ohms, very good ground (rich pastoral, midwest).

With no radials, I get a flat 50 ohm match at 3595 khz. Obviously this would indicate ground losses of approximately 25 ohms, if I'm thinking about this right. Also, predicted efficiency would then be 50 % (25/(25+25), indicating a 3 dB loss. Forgetting about fresnel region losses, this seems to be better than I had expected. 2:1 vswr bandwidth is very broad....broader than what I get with EZnec 4.x with a 25 ohm load in the base.

This means one of two things to me:

Either my ground losses are much higher than the 25 ohms I'm indirectly calculating, or I have made some sort of conceptual error in thinking about what the implications are of a 25 or 26 ohm feedpoint. All my references point toward a 25 ohm radiation resistance for my 42' vertical x 25.8 ft inverted L (with sloping top wire instead of flat top wire). What is wrong with my logic here? If the R(rad) is 25 ohms, and I measure a flat VSWR (on two other meters) at 3600 khz, then isn't the remaining 25 ohms, ground loss?

I also show about 37 ohms resistance and 0 ohms reactance at 3600 khz with my MFJ-269, which is really confusing, in that if I have 25 ohms for Rrad, then I have 13 ohms of ground losses. Further, 37 ohms is around 1.3 to 1. So I have two other vswr meters showing 1:1 at 3600, and the MFJ showing 37 ohms. This is a pretty large percentage difference.

I would be inclined to believe the 25.8 ohms predicted by both EZnec 4 and the Low Band DX'rs Handbook. In any case, I'll put out 4 radials tomorrow morning and repeat all my measurements, looking for narrowing bandwidth and lowered input Z as my ground losses decrease.

Ultimately, I'm going to put down 16, 66' radials, in steps of four, taking measurements of input Z (mfj-269) and vswr bandwidth for 2:1, at 0,4,8 and 16 radials. I'll report what happens as I go along.

Anywho, without any radials at all there are quite a few distant signals on 80m this evening, that are consistently louder on the newly installed inverted L, than on my Carolina Windom at 45'. Most signals as one pans the band, are louder (at 2 hours after sunset) on the C. Windom than on the radial-less inverted L, but ones from several states away are equal or better on the radial-less inverted L. Both seem to make good sense at this point. I sure will be interested to see the effects of 4 and then 8 and on up radials, but that is going to take a few days, because I don't want to

make radial changes unless I have access to low angle signals, which only happens at night or just before sunrise.

Tomorrow is radial day. I will be laying out 4 radials 65' long to begin with. I have resistance and reactance measurements every 50 khz as a baseline, before installing radials. 4 in the early morning, 4 more just before sunset, then 4 more the next morning, and the final 4 the next evening. #14 THHN stranded insulated copper wire for the radials, btw.

Depending on what I end up seeing for "effect" I'll go to 24 or 32 radials by winter....but only if the improvement is both measurable and "observable on the air"...radials are a pain in the rear (or more accurately, the knees) to put in.

What fun!

Bought a small boombox. It has no antenna connection screws, just a built-in antenna. It gets no AM stations at all, just static. I work in a big GM plant (all steel building). Nobodies radios get AM.

I mounted a car antenna on a bracket (isolated from the bracket with a rubber gromet) and mounted the bracket to a chain link fence 20ft from the plant. I hooked a coax center wire to the antenna base. I clamped the braided wire to the bracket. At the other end, inside the plant, I connected the center wire to the built-in antenna on the radio via an alligator clip. I still get no AM. I haven't hooked the braided wire to anything because I have no terminals on the radio. Do I hook it to any ground, such as an eletrical conduit or can I hook it to the radios battery ground terminals(I am not using the battery terminals because I am plugged into an outlet)? Am I far enough from the building? Do I need to be above the building? Is there a limit to how long my coax can be? Any advice is more than I currently have. Thanks...

113. Re: 80m Inverted L Initial measurements

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-03 11:47:20 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <dfc2g9$8a3$1@news.netins.net>
Source record: 71110

Starting point for the inverted L with sloping top loading wire.

45' high, 25.8' sloping wire at the top, 29 feet high at the far end. #12 THHN Insulated copper wire, stranded. Mounted 7" above the earth, directly to a 3' ground rod (strictly for mechanical support, as I had a prefab mount with 3/8x24 on one end and SO-29 on the other)

Predicted Radiation Resistance (Devoldere): 25.8 ohms, very good ground (rich pastoral, midwest).

I see I had confused feedpoint impedance and radiation resistance (after reading some more in Devoldere's "Low-Band DX'ing")

According to Figure 9-94, the radiation resistance for my inverted L is approximately 25 ohms. According to EZnec 4.1, source data says:

Impedance = 25.58 + J 1.872 ohms at 3600 khz.

When I measure the antenna with the MFJ-269, I get:

R=37 and X=0

If Devoldere and EZNEC are correct (although EZNEC may or may not be measuring radiation resistance), then my radial-less inverted L is showing ground losses of 37-25=12 ohms. If so, then my efficiency, without radials is:
25/(25+12) or 25/37 or approximately 67%.

Before installing radials this morning, I just want to make sure I'm looking at the right variables and interpreting them properly. 4 radials, laying on the ground, will be ready to install when the sun comes up. 4 more later in the day, etc., up to a total of 16 (the amount of wire I have ready to go). Each time I put down 4, I'll take another measurement with the 269. For kicks, I might take a measurement with just one or two first.

All YAGI elements can, and most are, center mounted on a conductive boom.

Reason: Voltage minimum.

You could use wood, but, man oh man, the problems that will surface
under weather condx.

Date: 2005-09-03 14:27:52 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <dfcbt9dij1@news.netins.net>
Source record: 71114

Question: Where was I taking my measurements.

I started out at the actual feedpoint...then put in about 55' of LMR-400,
and started a new set of measurements in the shack. Here is the latest data:

Radials 2:1 Fo 2:1 BW Z VSWR @ Fo
0 3340 3522 3920 580 36,0 1.3
2 3354 3524 3774 420 45,0 1.0
4 3419 3533 3741 322 60,1 1.2
8 3445 3550 3742 297 65,4 1.3

The formatting is bad, but in order, left to right:

Number of Radials
Lower 2:1 vswr point
Resonant Freq point
Upper 2:1 point
Bandwidth in kilohertz
Impedance as shown on the MFJ 269 at resonance.

I'm a bit confused by the rising feedpoint impedance with increasing number
of radials. That seems backwards to me.

73,

118. Re: 80m Inverted L Initial measurements

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-03 14:36:37 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <dfccdl$e3n$1@news.netins.net>
Source record: 71115

OK, here is my summary table for up to 8 radials, 66 feet long, insulated wire, laying on the ground: (all measurements at the shack end of 55' of LMR-400 coax, buried)

Radials 2:1 Fo 2:1 BW Z VSWR @ Fo
0 3340 3522 3920 580 36,0 1.3
2 3354 3524 3774 420 45,0 1.0
4 3419 3533 3741 322 60,1 1.2
8 3445 3550 3742 297 65,4 1.3

The formatting is bad, but in order, left to right:

Number of Radials
Lower 2:1 vswr point
Resonant Freq point
Upper 2:1 point
Bandwidth in kilohertz
Impedance as shown on the MFJ 269 at resonance.

I'm a bit confused by the rising feedpoint impedance with increased radial numbers, but the narrowing down of the bandwidth indicates decreased losses. It also indicates (since it continues to decrease), that I should add another 8 radials to see if I begin approaching the asymptote (sp?). The rate of change is slowing quite a bit.

Any input as to explanations and the data are most welcome.

...hasan, N0AN

p.s. Performance seems quite good for a VERY limited sample. A w6 this morning was 2 to 3 S-units stronger on the inverted L than on the 45' high Carolina Windom 80. An LU6 was coming in S9 with an S5 noise level, and responded with a 59+ signal report on the first call. A sampling of other signals prior to or shortly after sunrise is showing a clear superiority of the inverted L with 8 radials over the CW 80, at distances > 1500 km. Less than that distance and either antenna could have the upper hand until one gets to within the state of Iowa. I'll have to do more measurements to get a firm idea as to where the cross-over point is between the two antennas.

Indeed.

Unfortunately, I believe that you are at the mercy of your
instrumentation. I doubt that you can make meaningful measurements of
the differences resulting from the addition of a few radials at a
time.

The fact that you can't get correlation between measurements made on
the -same- antenna with different instruments is a problem. Until you
have two clocks that read the same, you don't know what time it is.

120. Re: 80m Inverted L Initial measurements

Newsgroup: rec.radio.amateur.antenna

Source record: 71117

I do have correlation now. The vswr meters and the mfj all read the same resonant frequency now, Wes. See my post that shows the data for 0,2,4,8 radials. While a given absolute value might be in error (a certainty due to inexpensive instruments), the trend is sound for bandwidth, but a bit strange for feedpoint impedance. (BW is narrowing but input Z is going up, with increasing numbers of radials.)

Ideas?

But the radio _does_ work outside, yes? If not you're out of luck with
that radio.
>

> battery ground terminals(I am not using the battery terminals because I
> am plugged into an outlet)?

Hooking it to the radio's battery ground terminal should work, if that
radio will work at all. If you can try the antenna installation with a
radio that has dedicated external antenna and ground terminals that
would be better - if it works with another radio and not yours then you
know that it's your radio.

> Am I far enough from the building?

Yes. You should be able to put the antenna right on the skin of the
building and have this idea work.

> Do I
> need to be above the building?

No, but it might help. Putting the antenna on a short mast (5-10 feet)
on the roof of the building would be ideal if you could get by building
maintenance.

> Is there a limit to how long my coax can
> be?

Not a limit, per se, but the longer your coax the more the signal will
be attenuated. Since your antenna isn't a significant fraction of a
wavelength long it will have a very poor match to your cable. Little
antennas like this look more like capacitive probes than like nice
healthy resistive sources. With a long cable any electric field around

the antenna will get split between the small capacitance of the whip and the large capacitance of the cable, so a long cable run will really pull the signal strength down.

The usual technique for good reception with capacitive whips like this is either to use a really short run of cable (like you see in a car) or to put a preamplifier with a high-impedance input right at the antenna and a low impedance drive to the cable -- then the signal down to the radio gets sent in a manner that's not attenuated by capacitive loading.

> Any advice is more than I currently have. Thanks...
>
Keep plugging away. I'd start with something known to work (like a radio right outside the door) and get closer to your goal with something that still works, until the radio is right where you want it to be and working the way you want.

I could believe that it would be more cost effective to find an
existing AM radio that happens to already incorporate a ferrite rod
antenna and just go with that. If that wont work, then hopefully, it
will also have a single terminal as does the radio you are now trying,
and you could run a long wire.

Get about 100 to 200 feet of insulated hook up wire and run it from
the radio antenna terminal out a window, or whatever, and run it out
as far and as high as you can, staying away from metal objects.

Your idea of using a car antenna with a coax line is hopeless - forget
that.

123. Re: 80m Inverted L Initial measurements

Newsgroup: rec.radio.amateur.antenna

Source record: 71120

If your antenna is over a PERFECT ground, an EM mirror, then the mutually coupled impedance between the antenna and it's image antenna gets to be a bit difficult to calculate or estimate. The Apex and it's image are 80 feet apart. That is 107 degree spacing, and the ends are 77 degrees apart. The mutual impedance along the length of the antenna changes due to the difference in phase shift.

Change from perfect reflecting ground to 'real' ground with varying conductivity and permittivity as a function of length, width and depth and the problem becomes much more complicated.

Your measurements, in your location, with your installation indicate, to me, that your 8 radial solution is starting to converge to best solution. I say this for two reasons. Your 2:1 VSWR bandwidth is narrow and your Z is approaching 73 ohms.

I would use the eight radial solution and trim the antenna length to your desired center frequency. Remember, a 2:1 VSWR indicates that 90% of your energy is going into the antenna.

For the best analysis of your installation, the soil characteristics would have to be known and controlled for several wavelengths square and approximately 1/4 wavelength deep. Your radials [counterpoise] are simplifying and stabilizing your solution.

Roy Llewellen is much better qualified than I to proceed deeper into the EM Physics regarding all the possible interactions. If the science of what's happening is your interest then contact Roy off-line [Roy, sorry to volunteer you without your consent]. If a brief understanding of possible contributing EM effects is your desire, then I hope this contributes to your understanding.

==========

SWR increases the further the impedance, either HIGHER or LOWER,
departs from 50 ohms.

The only way to measure antenna input impedance is by means of an
impedance bridge. Try one of the small antenna analysers.

Has anyone Eznec description file for magnetic loop antenna?
Please send it to my mail (remove BEZSPAMA from e-mail address).
I want to simulate this antenna in Eznec software to see 3D pattern. For dipole it is simple but magnetic loop has two loops and capacitor.
Please help. I checked on google and all people talks that they made simulation for this antenna but how they have done it I don't know.
I made two loops in Eznec software and I placed source on small loop and load (capacitor?) on big loop. I can't achieve low SWR. I get some pattern but I think that I missed something.
In real life I made this antenna and she works very good with low SWR :-)

Source record: 71123

That is exactly what I'm using Reg, and why I"m puzzled. I'm getting rising feedpoint impedance with increasing numbers of radials. The 2:1 bandwidth is getting narrower, as it should, but what accounts for the increasing feedpoint impedance? MFJ-269 antenna analyzer is what generated the table I posted earlier.

Very strange?

Fedthecat wrote:
"I still get no AM."

A typical telescopic automobile antenna presents an impedance of about 5185 ohms at 1MHz because it appears as a 50 picofarad capacitor according to the "Radiotron Designer`s Handbook".

This is about a 100 to 1 mismatch to 50-ohm cable.

The The coax used with car radios for the AM broadcast reception has a tiny-diameter center conductor and a large diameter outer conductor for a high-impedance Zo so as not to lose the signal to mismatch.

There is no magic in the car radio whip beyond its stiffness to hoold its position..

Wavelength at 1 MHz is 300 meters. A resonant 1/4-wave antenna is 75 meters and impractical. Any car antenna s going to be too short, be capacitive, and have a high impedance.

Coax of the 50-ohm or 75-ohm variety is available in long continuous lengths. The right length may alreaady be in place.

A tuned loop receives and reradiates very well. Fedthecat needs two tuned loops, one outside where the signal is, and one inside where the receiver is. A couple of turns should be wound on each loop to make connections to the cable between the loops. A twisted pair could interconnect the loops but may be more susceptible to noise than properly grounded coax.

Connect the two loops, tune them to the desired signal and position both for best reception.

Best regards, Richard Harrison, KB5WZI

Interesting observations.

The 2:1 swr points are only being mentioned to show that the bandwidth is narrowing with increasing number of radials. That makes sense.

What doesn't make sense is the increasing feedpoint Z at resonance in response to increasing radial numbers. There could be some minor trimming, but 3 or 4 ohms reactance is probably close enough...the antenna is near resonance and the resistive component is not likely to change much by trimming the last 3 or 4 ohms of reactance out. The problem is, I can't explain the the 65 ohm feedpoint impedance.

Most installations, start with a Z too high (because it includes ground losses), and as radials are added, the feedpoint Z drops (as the loss resistance disappears). This is the classical 1/4w ground mounted vertical case. You know when to stop adding radials when the measured feedpoint impedance at resonance is equal to the Z of the antenna over a "perfect" ground.

Another way to accomplish the same thing is to keep adding radials until the 2:1 vswr bandwidth no longer narrows. I think I'm approaching that right now.

The anomaly I'm trying to deal with is why the feedpoint Z has increased as I went from 0 to 2, to 4, to 8 radials, when it should have decreased. I wouldn't care a whit, if the terminal (end point) feedpoint Z was 65 ohms resistive with no reactive component.

This is a technical element that I want to understand...no further changes are likely to make any real difference in performance. What is it Johnny Cochran said, "If the data don't fit, I just won't quit."? <vbg>

I have done this dozens of times inside of steel structures, mainly aircraft hangars.

Forget the boombox. You never WILL get it to work. Go down to the auto salvage yard and get an automobile radio that was made in the last ten years or so. They are intended to be fed with 50 ohm coax of any reasonable length -- I've hung antennas into wingtips that are 50 feet from the radio and fed with RG-174 (the little tiny stuff) and the radio works just fine.

You will need a 12 volt power supply or a battery/battery charger setup for a power source and external speaker(s). Don't forget to buy a motorola plug for the coax going into the car radio antenna jack.

Hasan,

I think you are measuring the input impedance of an Inverted-L against a system of ground radials.

You are trying to estimate the input resistance of the ground radials by subtracting the CALCULATED radiation resistance of the Inverted-L from the measured antenna input resistance.

Excellent, there is no better way of doing it!

First of all, the overall length of the antenna must be 1/4-wavelength resonant at the testing frequency such that its input impedance is PURELY RESISTIVE. The measured input resistance, of course, will be greater than the calculated radiation resistance referred to its base. The difference between them is the required input resistance of the ground radials.

The hard part of the exercise is calculating the radiation resistance referred to the base of the Inverted-L. The radiation resistance is a very complicated function of the dimensions, overall length and height, of the antenna.

However, for the purposes of estimating ground loss resistance, (it changes with rainfall and temperature of the season), the following approximation for radiation resistance is good enough.

RadRes = 18 * (1 - Cos(Theta)) ohms,

where Theta is an angle = 180 * H / (H + L) / Lambda degrees,

H = height of vertical portion of Inverted-L,
L = length of horizontal portion of Inverted-L
and Lambda is the free-space wavelength.

This formula applies ONLY when L+H is 1/4-wave resonant. Which is the condition under which you are working if you are doing the job correctly.

You will not find the formula in the books of bible-writer Terman. Nor in any of the works of the other regular gurus. If you ask from where it came from, it came from one of my old notebooks and I worked it out for myself, years back.

Bear in mind it is only an approximation. It would take 6 months to work out how precisely accurate it is and I don't have the time. But it's as least as accurate as you can make impedance measurements. I do hope I have copied it out correctly.

By the way, as the number of your radials increases and the ground loss resistance gets very low, don't be surprised if you calculate negative values of ground loss resistance.

I think your main problem is that the boom box antenna isn't connected to the AM part of its radio at all. The whip antenna is probably used only for FM. For AM, the boom box likely has an internal ferrite rod antenna. Some of the other people on this newsgroup should be better able than I am to suggest ways of coupling to it with your external antenna. It might or might not be successful.

The best solution is to get an auto radio, which is designed to use a short external whip antenna on AM. You'll need a speaker and a 12 volt power supply to go with it.

If you're going to use coaxial cable to connect to the antenna, you should put the antenna as close to the building as possible (to keep the coax short), and use the special coax which is used with automobile radios. The location of the antenna isn't very important, as long as it's outside the building.

I've seen the coiled "antenna augmenters" used for fringe are reception.
Never bought one or tried one. When I recently tried a small boom box in my
new metal shop I had nearly no AM reception. Remembering those fringe area
antenna coils I wound a coil about 8 inches in diam. from 50' approx. of 14
ga. insulated wire and laid the coiled portion on top of the radio and hung
a few feet of the wire out the shop window. Didn't turn it into a miracle
radio, but stations barely hearable came up to the listenable level. I
wonder if a much longer coil (coil with a lot more wire in it) and a longer
tail hung out the window would raise my reception to an even better level.

I'm calculating as we speak, thanks tip, I'll see if the numbers line up. Also, I'm going out to the feedpoint to do some measurements as the 55' of coax is transforming the impedance at the feedpoint. Gotta beat the misquitoes, the come in swarms at local sunset. 73

...hasan, N0AN

45 high by 25.8 feet are the antenna dimensions.
BTW is lambda in meters (free space wavelength)? I got something on the order of 11.28 ohms, but that was with a new calculator that I'm not sure of the precedence of operations in. Very fancy, but completely backwards from all the other calcs I had previously owned. No wonder it was cheap.

Hassan,

Where are the radials (above ground, buried, how far)?

I think you told us that they radial wire is insulated, is that
correct?

Why did you choose 66' long radials?

Owen

Message-ID: <dfd9km$u7k$1@news.netins.net>
Source record: 71032

Owen,

Wire is laying on the ground, insulated, as it doesn't make any difference and lasts longer. 66' is 1/4 wave at 80m which is always a safe starting point. I probably could shorten them and do more. I intend to put in at least 8 more for a total of 16.

I found out why the input Z was going up as I put more radials in...I was measuring at the end of 55' of LMR-400 (as opposed to the measurements I took when I was outside originally tuning the antenna.), and that was acting as a 1/4 wave transformer.

I just went outside and connected through an 18 inch jumper to the MFJ-269 and got the following measurements:

2:1 VSWR Low freq Point: 3460 khz
2:1 VSWR Hi freq Point: 3801 khz
2:1 VSWR Bandwidth: 341 khz
Fo (Resonant freq) = 3560 khz, 40 ohms resistive, 0 ohms reactance

3500 32,9 1.6
3550 38,0 1.0
3600 44,9 1.2
3650 52,19 1.4
3700 57,30 1.6
3750 63,35 1.8
3800 69,39 2.0

Above table: freq, R,+/- j, VSWR, all taken from the MFJ-269

If the radiation resistance is 26 ohms and I measure 38 ohms feed impedance at resonance, then apparently I have 12 ohms of ground loss, for an efficiency of:

26/(26+12) or 26/38 = 68%

At least, that's where I'm at for the moment. Time for another 8 radials.

That 1/4 wave transformer (55' of LMR-400 between feedpoint and shack) that Tom, W8JI, pointed out, makes a big difference in my confusion...at least it all makes sense now.

73,

2:1 VSWR Bandwidth: 341 khz
Fo (Resonant freq) = 3560 khz, 40 ohms resistive, 0 ohms reactance

3500 32,9 1.6
3550 38,0 1.0
3600 44,9 1.2
3650 52,19 1.4
3700 57,30 1.6
3750 63,35 1.8
3800 69,39 2.0

Above table: freq, R,+/- j, VSWR, all taken from the MFJ-269

If the radiation resistance is 26 ohms and I measure 38 ohms feed impedance at resonance, then apparently I have 12 ohms of ground loss, for an efficiency of:

26/(26+12) or 26/38 = 68%

At least, that's where I'm at for the moment. Time for another 8 radials.

That 1/4 wave transformer (55' of LMR-400 between feedpoint and shack) that Tom, W8JI, pointed out, makes a big difference in my confusion...at least it all makes sense now.

Ok, you have figured out the coax transforms the impedance. If indeed
the Z at the generator end of the coax was 36+j0 (ie it was resonant
at that point), then I make the load Z ~ 62-j5.

This will confuse your efforts to infer an effective ground system
impedance, and losses.

Another point to consider, instruments like you are using (in my
experience) are more accurate near to 50+j0, and you may get better
results by bulking up the feedpoint Z with a known fixed resistor to
exploit the better measurement accuracy around 50+j0.

Sorry that should have been 69-j7 (above calc was for one of your
other figures, 40+j0).

Well, I think that you're expecting the thing to behave just like a
monopole but it's not a monopole.

When I model your configuration (except for insulation) I get a
resonant freq of 3.573 MHz and R = 23.3 ohm over a Mininec Pastoral
ground.

Making it a full height monopole it must be 67' high and the feedpoint
R = 37.

I believe that I read elsewhere that you are taking data at the input
end of a coax line. Unless you have characterized the line and are
backing out its effects you are going to remain mystified.

Also it you have any other antennas in the area that can be an issue.

I'm a believer in modeling but unless -everything- is accounted for,
reality and the model won't correlate.

For example, I have a Cushcraft AV-80 vertical that I've used as a
test bed. This is a 2" diameter, 36' high pipe with four 3' top hat
wires. Cushcraft supplied a base-loading coil, which is not used.
The antenna is ground-mounted on a 16" square aluminum plate with
sixteen 50' radials. Installing radials at this location is a
"sticky" proposition and the soil is best characterized as sand
(decomposed granite actually).

I have measured the base impedance with both an HP8405 Vector
Voltmeter and coax bridge that was calibrated with an open-short-load
(OSL) method as well as a much faster N2PK vector network analyzer,
calibrated the same way. All measurements were taken at the base of
the antenna. This is an on again off again project (currently off)
with the goal of determining the effectiveness of the radial field.

The data are very repeatable and believed to be correct; however, I cannot construct a model that replicates the physical antenna. For example the curve on the Smith chart of the measured data has a little bump in it and the resonant frequency is slightly off from the model. The "bump" isn't a full-blown resonance loop, but it looks like it's trying. Here is a plot from 1.5 to 15 MHz. The resonant freq is 5.5 MHz.

http://users.triconet.org/wesandlinda/Vertical_Z.gif

As you can see from the photo, there several other "verticals" in the vicinity as well as my 45' foot tower with beam and wire dipoles 90' away.

Fedthecat

Some things you might want to consider are:
The thing we refer to as antennas on cars arent as much antennas as they
are probes of the currents flowing on the body of the car.
The coax between the "car antenna" and the radio is a capacitor to ground
that shunts the signal at the receiver input. Car antenna designers keep
the length of the feed line as short as possible and make it's capacity as
low as practical, which coincidently is the highest characteristic impedance

VW (and probably alot of others) have been installing amplifiers at the
base of the "car antenna" so the coax cable capacity is not a problem.

There are alot of web sites that discuss how to build an AM loop antenna
and how it can be coupled to the boombox. The loops work without the
amplifier.

You need to open up the boombox, locate the ferrite rod and wrap 3 or 4
turns of insulated wire around it. Run the insulated wire to a connector you
mount on your radio. It could be a bnc or an "F" connector.
Install the mating connector on your coax to plug into your radio. Now
outside the plant you can try the auto antenna, but I think a piece of wire
15ft to 50 ft ran along the fence, connected to the center conductor, with
braid
grounded.

I came across an interesting antenna the other day on the web. It called for four radials for each band that one would want to use it on. In order to protect the lawn mower I would like to bury the radials. If I use insulated wires for the radials can I bury multiple radials for different frequencies in the same trench. I would rent a small trencher like they use for underground power and utility feeds, make four trenches and drop in the radials, then cover them.

Thanx for any responses.

Run a LONG extension cord just outside your office window. Plug in the radio and put an umbrella over it. Turn it on and tune in your favorite AM broadcast. Turn the volume up to maximum. Go back inside. Find a suitable drinking glass and place it on the wall (open side toward the wall), just opposite the radio you've just installed outside. Place your ear on the other end of the glass...Enjoy. If your boss asks you, "What the flock you are doing?"...just tell him that you are following advice you got from rec.radio.amateur.antenna.

If this sounds like to much trouble, just get to used to FM broadcast.

"hasan schiers" wrote (I'm still waiting for
> clarification on your formula, btw)
>
==========

There's a mistake in the formula. I copied it incorrectly from my old notebook.

The wavelength Lambda doesn't come into it. No wonder you asked what units Lambda is in.

The correct, more simple, formula is -

RadRes = 18 * (1 - Cos(180 * H / (H + L)) ohms,

Where H = Height, L = Length of horizontal section, and the angle is in degrees.

Your antenna is 45 feet high and 70.8 feet overall length. (It doesn't matter what the measurement units are. It's just a ratio.)

And so your radiation resistance, at 1/4-wave resonance, is 25.4 ohms, give or take a few ohms.

The only thing I'm unhappy about is making impedance measurements at the other end of 55 feet of coax. You need to know the exact Zo and velocity factor and length of this cable, plus some accurate calculations. The technique is fraught with error.

Get your hand-held antenna analyser right to the bottom end of the antenna wire, on the R + jX range, and immediately adjacent to the focal point of the radials. And hope you don't get interference from the local, high power, MF broadcast station. But you are already aware of this and I mention it for the benefit of the lurkers.

I assume you measure SWR only to estimate antenna bandwidth. At the other end of 55 feet of coax anything can happen to SWR. But if bandwidth decreases as the number of radials increases then at least it is going in the right direction. I don't think you will squeeze any other information out of it.

Reg, G4FGQ

Hasan,

If you download program ENDFEED and insert details of your antenna and ground radials system, you will find the impedances closely agee with what you actually get. (I'm always very happy when this happens.)

Enter the exact 80-meter band frequency at which you have found your own antenna to be 1/4-wave resonant. Then slightly prune antenna height until the program says the antenna is 1/4-wavelength long. Very likely your antenna horizontal section is sloping.

As a final check, do with the program what you have done with your own antenna, and subtract the RF ground resistance from the antenna input resistance to give the radiation resistance. (The radiation resistance is not displayed by the program although, obviously, it is used internally.)

The primary purpose of the program is to calculate the L and C values of three different impedance-matching networks (tuners), which you may find useful. Radiating efficiency is also calculated and displayed.

Download ENDFEED, an old program of mine, from website below.

for an 80-40-20 dipole you don't need 'traps' to shorten the 80m piece you need 'loading coils'. 'traps' have a resonance that effectively cuts off the section of the wire past them making the inner part resonant on the higher frequency, so you need 'traps' for 20m and 40m. 'loading coils' are simply an inductance that makes the section appear longer than it physically is.

From: Scott <acepilot@bloomer.net>
Message-ID: <A8qdnVXBidCLfofeRVn-pQ@bright.net>
Source record: 71049

Traps will not shorten your antenna appreciably. To shorten an antenna, you use loading coils, which are just wires turned into a coil. Traps consist of a coil and a capacitor in parallel with each other that stop signal flow through them at a specific frequency.

So, if I understand what you want, is that you want the total antenna length to be shorter than a normal half-wave dipole on 80M. The best place to find the info you seek is in the ARRL Antenna Handbook. They should be available at http://www.arrl.org/

You will first need to determine what length you want the antenna for 80M to be. Then, you will want to look in the chart in the book. You will want to place the coils as far out from the center of the antenna as practical. The further out the loading coils are from center, the larger amount of inductance they need to be to a point where it is impractical to build them. Usually putting them at the 50% point is fairly easy but, if you are going to have a 40M trap in the antenna, these would be right about where the loading coils would go, so, just move the loading coils outward from center, just a few feet past the 40M traps. You will most likely have to adjust the wire lengths from the loading coils out to the ends of the antenna to find resonance.

that is what i said, but in regards to 'shorten the length' of the 80m part
it is a loading coil he needs.

Outstanding, Reg. Your formula for Rrad agrees completely with the graph in Devoldere's book. I will make a special effort to copy the formula down correctly and put it in the subdirectory of my hard disk that has all your other programs.

I already figured out the 1/4 wave transformer problem, so I went out in measured again directly (18" jumper) the feedpoint impedance and got much more realistic readings.

I recall from reading some of your other posts when people were wringing their hands about what antenna they could put up in a given circumstance. You advised the inverted L in the garden. When I started work on this project (whose goal was a decent DX antenna for 80m), I thought of your comments on many occasions.

As you noted, I'm doing the 2:1 VSWR bandwidth measurements strictly to look for the point of diminishing returns on laying the radial field. It is quite clear at this point that 8 is not quite enough, but 16 should be more than adequate to get me within 1 dB of the idea.

It has been a fun experiment so far, and an enlightening discussion. Thanks so much for your formula and other comments. Most helpful.

> Has anyone on here tried this?
>
> John
> m1jta

==========

John,
I have used 3 or 4 feet alumininium alloy tubes as earth rods, on and off, for many years. I have found them just the same as any other or metals - ie., no bloody good.

Electrically, at HF, a 3 or 4-feet earth rod is no better than a single, thin, radial, shallow-buried, horizontal wire of the same length which is much easier to install.

The resistance to ground has nothing whatsoever to do with the conductivity of the metal or surface corrosion products. It has everything to do with the resistivity of the soil in which the rod is embedded. ie., the soil in the immediate vicinity of the rod.

Resistance to ground depends almost entirely on rod length and is only very slightly dependent on rod diameter.

Only old wives believe resistance is related to surface area of the rod or electrode and dig great holes in their back gardens to bury unwanted, scrap, hot-water cylinders. They would do better by approaching their local scrap metal merchant.

A 3 or 4 feet rod in typical garden soil has a resistance to ground of the order of 100 to 200 ohms and by itself is useless.

To locate one rod immediately next to another does next to nothing regarding ground connection resistance. A pair of rods must be spaced apart by at least twice their length before the resulting ground resistance approaches half the resistance of one rod.

A collection of a number of rods must be spaced apart by many times greater than their depth of burial to obtain the full benefit of all being connected in parallel.

Consequently, the connecting wires from rods to a focal point themselves constitute a good system of shallow-buried radials and the short rods at the ends of the radial wires can be dispensed with. Exactly the same result can be achieved just by extending the radials by another, insignificant 3 feet. The rods are both wasted effort and wasted copper (or aluminium).

Boy, Reg, that last sentence describes EXACTLY what I have been attempting to do, squeeze the last bit of information or inference that I can make of the data collected. Your formula works perfectly for me, giving the same results on this fancy new calculator. It is formula based (which I am not used to), so the data entry is backwards from what I'm used to (RPN). Once I entered your formula into the calculator just as you show it, left to right, it produced the expected 25.4 ohms. That is one handy formula indeed! Who knows the boundary limits for its accuracy, (only the creator would know that), but in the case of my particular antenna, it is right on the money and agrees with the "book" based graph that gave me the original value of 25 ohms for a 0.16 wavelength high quarter wave inverted L. It's nice to have convergence!

The traps -do- shorten the overall length of the antenna. Because the
80-meter part -is- the total length, I would say the traps shorten it.
In other words, below their resonant frequency they are inductive and
function as loading coils.

Without looking at the book I would say yes. If you put 1 A into a Z
and 25.65 V @ 4.18 degree develops then that Z = 25.58 +j1.872

i don't know what ladder loc is, but i am curious what a 'center fed zepp' might be? could that possibly just be a dipole?? classically a 'zepp' antenna was a 1/4 wave wire trailed from a zeppelin airship end-fed with a 1/4 wave feedline that essentially acts as the other half of the dipole.

Vinnie-

The usual configuration of an 80-40 trap dipole has 40 Meter traps at
about 33 feet from the center. The remaining wire is less than for a full
half wave on 80 Meters since the 40 Meter trap acts as a loading coil on
80. Length may be less if you have 20 Meter traps as well.

If you have enough room for a little over 100 feet, you may not need any
additional loading coils. You also might reduce the total length some by
increasing the inductance-to-capacitance ratio of the traps.

Thanks to all for your advice. I'll try your adeas and see what
happens.
As for people that say 'Get used to FM' when a person is trying to get
AM, why don't they get used to drinking water from a mud puddle? The
reason is that a mud puddle offers none of what they want to quench
their thirst. Why would I want to listen to FM when FM has nothing to
offer except music? If all I wanted was music why would I get FM when a
cd play would get me what I want with no blabbering dj. I requested
info on a way to get AM at work because AM is what I want. Again,
thanks to all the people who offered real thoughts. :'}

167. Feeding a wire loop antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-04 19:21:01 UTC
From: Antonio Vernucci <vernucci@tin.it>
Message-ID: <xOHSe.18359$4g5.1241684@news4.tin.it>
Source record: 71063

At my summer QTH, I cannot do more than using a "stealth" thin-wire antenna.

For operation 40 through 10 meters, I had fairly good results using a plain 30-ft wire and a tuner. But I do not like that solution because, in my case, access to earth (water pipe) is not convenient.

So, I decided to switch to a symmetrical antenna that does not require an earth connection. I have then mounted a square wire loop, about 15 ft each side, fed with about 5 feet of 450-ohm ladder line. The antenna impedance varies a lot across the desired frequency range, but it can be easily matched by my tuner on all bands.

The antenna being symmetrical, and the tuner asymmetrical, it is advisable to use a balun. Three solutions come to my mind:

1) using an off-the-shelf (e.g. MFJ, Vectronics, etc.) toroidal ferrite balun at the tuner output. I do not like this solution because, on some frequency bands, the antenna impedance gets very high, and I am not sure on how the RF transformer behaves under those conditions

2) putting an RF choke at the tuner output. The choke could be built by winding several turns of 450 ohm ladder line over a fat ferrite rod (obtained by glueing several small rods to each other)

3) putting an RF choke at the tuner INPUT, by winding several turns of the RG-58 cable connecting the transceiver to the tuner on a ferrite rod. In this way the tuner body would be "hot", but this may not be a real problem

Any comment on the pros and cons of the three approaches would be welcome.

Hi Dave,

You are correct except it was a 1/2wave wire end fed with 1/4 wave feed line.
But today the center fed dipole cut for the lowest desired frequency and fed with open or ladder line is being call the center fed zepp by many..
I've also heard it called the Double Zepp. But the Doublet would be better terminology to use. In any event he would be talkig about a dipole I assume cut for 80m fed in the center with open wire parallel line of some sort and used with a tuner on all bands.

Hi Tony,

I used the third method you mentioned for several years with good sucess.
I like that option because once the tuner is match the choke balun sees a
contant impedence and is not so likely to cause problems. However most

tuners use the opposite the Balun on the output. Except the new MFJ
balanced line tuner.

in any event let us know what you come up with

Thanks Dave,

I agree that the third solution should work well. But I will not be able to test it until I will be back there, and this will not be before several months from now.

I have verified that my Daiwa tuner has plastic tuning knobs and that both variable capacitors also have a plastic tuning axis, so the proximity of my hand should yield a limited error on the tuning point.

It is in free space. Lying on the ground isn't free space.

Were the radials buried, depending on the ground, 66' might be more in
the vicinity of an electrical half wave. Suspended a short distance
above the ground might be close to an electrical quarter wave. Yours
will be somewhere between depending on the installation variables.

It would be interesting to measure the impedance and find the
resonance of a pair of opposite radials.

I don't think he will have any problem getting that antenna in at under
100 feet with out using extra inductance at the ends. My 75M dipole
trapped at 40M is right around 100 feet, I think. If he adds 20M traps
they will surly shorten it even more.

The question you ask is very broad.

I suggest you get a copy of any ARRL Radio Amateur's Handbook and
start there. If your interest is not high enough to pay the price of
the book, most Public Libraries have copies to loan. At this point,
the year of publication is not likely an important consideration.

After that, rephrase your question and come back to the group.

I had a similar problem about 5 years ago- I was working part of the day in a small lab and the rest in the warehouse- both in a steel building. What worked was to drape a longwire out the window (lab) or up into the rafters (warehouse), then, to kep things simple, wrap the endof the wire around the radio 2-3 times. It wasn't elegant, but it alowed receptiopn of the local Red Sox outlet!

There are two other books to look for:

Yagi Antenna Design by James L. Lawson, W2PV
Physical Design of Yagi Antennas by David B. Leeson, W6QHS

These will answer just about any question you might have about Yagis.
Both are published by the ARRL.

Roy Lewallen, W7EL

179. Re: 80m Inverted L Initial measurements

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-05 01:52:35 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <dfg8d5hpr1@news.netins.net>
Source record: 71075

Final Measurements:

I added 8 more radials this evening for a total of 16.

Radials 2:1 Fo 2:1 BW Z VSWR @ Fo

8 3460 3564 3801 341 40,0 1.2 (at antenna)

16 3524 3580 3800 276 31,0 1.7 (at antenna)

Fo is the resonant freq, 2:1 are the lower and upper 2:1 vswr frequency points.
BW is the 2:1 SWR Bandwidth in Khz.
Z is the R +/- j impedance read from an MFJ-269 antenna analyzer at the feedpoint.

Since the radiation resistance of the antenna is known to be 25.4 ohms:

Efficiency with 8 radials: 25.4/40 = 63.5% or ground loss = 1.97 dB
Efficiency with 16 radials: 25.4/31 =81.9% or ground loss = 0.86 dB

Additional info, 2:1 VSWR Bandwidth in Khz:

0 Radials = 580 khz
8 Radials = 341 khz
16 Radials = 275 khz

So, both "traditional" considerations of a 1/4 wave vertical have now been satisfied:

Increasing the number of radials decreased the feedpoint Z, approaching the nominal 25.4 ohms radiation resistance of the antenna.

Increasing the number of radials from 0 to 8 to 16, narrowed the bandwidth from 580 to 341 to 276 khz respectively.

The SWR at resonance is worse with 16 radials than with 0 radials (higher ground losses mask the reactance at the feedpoint)

16 Radials over very good Iowa black loam yields an efficiency of approximately 82%, and I see no reason to further increase the number of radials to recover .86 dB...and of course, it would probably require doubling the radial number yet again, to 32 to get half way there.

I'm now satisfied that the antenna behaves as expected and that the numbers are credible, but not absolute.

Time to play on the air some more. So far it is getting out very well.

Thanks to all of you for your input, I've learned a lot by playing. The TLE on-line calculator is a jewel! EZNEC 4.1 got me in the ballpark. The three most valuable lessons learned: beware of an unintentional 1/4 wave transformer (coax); Reg's clever formula for calculating radiation resistance of an inverted L, using simple trig functions, and 16 radials on 80m are quite sufficient OVER MY TYPE OF SOIL.

>
>Vinnie S.

Thanks for all the responses, but I seem to be more confused because it seemed I got differing opinions. As I said, I am a beginner at antenna theory. The frequencies I am trying to make an antenna for, are centered at 3.875, 7.225, and 14.250. Those are the center for the phone frequencies on the US bands. I wanted to shorten the 80 meter band antenna. I would have kept the 40 and 20 at the specified lengths. I guess I will buy the ARRL book. But they also make a long wire classic book. I might get that instead. .

Reg, G4FGQ wrote:
"The rods are both wasted effort and wasted copper (or aluminum)."

Likely so.

Radials are placed to capture displacement current to and from the vertical radiator, to prevent its travel at a high densitY in the earth where it would cause high loss.

B, L, & E found that more radials were better than longer radials. More radials put the displacement current capture closer to the vertical radiator where its density is higher. Radials need extend outward only as far as there is any current or until a point of diminishing returns is reached. At great distance from the vertical radiator, the earth`s crust, which may be affected, has a great cross section, so current density is low and so are losses. There is much less displacement current to deal with near the ends of radials. Displacement current is low near the ends of the radials and the earth out there has a large cross section and a low resistance. Due to skin effect, the closer to the surface, the higher the current. This is especially true at high frequencies.

I sent too soon.

The problem with ground rods at high radio frequencies is that depth of earth renetration may be low as compared with length of the ground rod. Contact that counts is that which connects with the current path.

There is a special problem with the aluminum material itself of the ground rods mentioned by the questioner. Aluminum, zinc, and magnesium are galvanic anodes used for cathodic protection of less active metals.

A copper ground rod is likely to last forever in the soil. An aluminum ground rod is likely to soon be sacrificed in its attempt to protect other connected metals in the same galvanic soup.

Message-ID: <24snh19iu141gghh6iamqv9peh8q7649gd@4ax.com>
Source record: 70982

I just bought a very old, verticle antenna. The ant. is aluminum and very coroded.

Is this just a cosmetic problem, or will the corosion affect the radiation/reception of RF?

Since the insulation on wire antennas doesn't affect their effectiveness, I'm thinking the corosion wouldn't be a problem; but my working-class logic has gotten me in trouble before. <G>

Will painting an aluminum antenna decrease it's effectiveness, or not matter?

Thanx-

Bob Sawyer wrote:
"I`m thinking the corrosion wouldn`t be a problem;--"

I think Bob is right.

Paint doesn`t help much, but it doesn`t hurt. You never see a new microwave dish that isn`t painted before shipment, mostly for appearance, but the paint inhibits corrosion too.

Aluminum spontaneously and rapidly forms oxide on its surface from contact with air. Surface oxide is a barrier to further oxidation. A painted dish is already oxidized before it is painted.

Rapid oxidation was one of the problems with aluminum house wiring. Sound electrical connections were hard to make and keep. Depending on the alloy, aluminum oxide (alumina) has such a high resistance that it is used as an insulator at high temperatures. Fretting corrosion is caused by interaction of aluminum with other metals and creates corrosion problems (extreme resistance) at junctions.

Aluminum is a satisfactory material for antennas. Witness the millions of outdoor TV antennas. High resistance of the thin oxide coating is not incapacitating.

Best regards, Richard Harrison, KB5WZI

You and Bob are correct. However, I do hope the previous owner of the antenna used an anti-seize compound on the joints, or else the new owner will have a dickens of a time taking the antenna apart.

The only point at which corrosion will affect the performance of the antenna
is if the corrosion has gotten into any of the mechanical joints of the
antenna. Corrosion on the elements will not be a factor.

Source record: 70990

I run a 130' dipole fed with ladderline down to a balun , then a coax stub to the tuner.

During a recent storm, one side of the antenna broke, or was broken by a falling limb---whichever.

The easy fix is to solder the pieces together, while bracing them physically.

This would make the side where the break was approx 1' shorter than previous.

Will my tuner compensate for a 1' assymetrical load?

Any reason not to do this, insofar as loading/performance?

The main worry with oxidation is at the joint(s).
Clean the connections where the transmission lines are attached - and if the antenna consists of more than one section, clean and penetrox the joints where they are connected.
Otherwise, a little cosmetic oxidation shouldn't hoit. ;-)
I'm not sure about comic oxidation or cosmic oxidation.

The best answer I've seen, based on current research is:

N=(SQRT(2*PI*L))/A

N equals the square root of the quantity 2*PI*L divided by A, where:

N = optimum number of radials for high efficiency
L = amount of wire available in meters
A = distance between wire tips at the far end (a measure of radial density)

A = 1.3 for 95% or greater efficiency (approximation) read article for more precise values.
A = 2.6 for 85% efficiency (approximation)

Example 1:

You have 500 meters of wire available. How many and how long for the two values of A?

N = (SQR(2*pi*500))/1.3 = 43 radials. Length = 500/43 = 11.6 meters

N= (SQR(2*pie*500))/2.6 = 22 radials. Length = 500/22 = 18 meters

Example 2: (you have space constraints and the max radial length available is 15 meters)

How many radials are required and how much wire is required?

The circumference of a circle with a radius of 15 meters is 2*PI*15 or 94.2 meters. With the tips of the radials seperated by 1.3 meters we have 94.2/1.3 = 72 radials. If we go for slightly more loss, we have 94.2/2.6 or 36 radials, 15 meters long.

Now you can plug in your own limitations for radial length, and get a feel for how many of them you will need for 95% efficiency (A=1.3 meters) and 85% (A=2.6 meters).

This info was presented in some ARRL publication, as I recall, and is also presented in the 4th Edition of "Low-Band DXing" by John Devodere.

Vinnie-

One thing isn't clear. How short do you need the total length to be?

I think everyone is in agreement that a trap dipole is shorter on the
lower band than a simple dipole would be for that band. The trap acts
like an inductor below its resonant frequency, so the part of the antenna
beyond the trap is electrically lengthened on the lower band(s).

Therefore, the 20 Meter traps would be at the proper places, around 16
feet each side of center. However, the 40 Meter traps would be closer to
the center than for a simple dipole, due to the inductive effect of the 20
Meter traps. Similarly, the added wire for 80 Meters is less than for a
simple dipole due to both the 20 and 40 Meter traps' inductance.

You may find that the resulting length of a dipole with both 20 and 40
Meter traps, is short enough for your needs.

While driving home from work, flip though the AM stations and find the one
you like best.

Do volunteer work for that station untile you understand radio engineering
well enough to become a station technician there.

Apply for such a position at that station.

Once you get the job, turn in your two week notice at your current job.

Once soundly employed at WAMW, tune in your radio for your work station and
enjoy.

I appreciate Walt, W2DU`s kind words regarding my posting about ground rods and radials.

I did not recommend any particular number or length of radials. RCA`s Brown, Lewis, and Epstein examined how many and how long ground radials should be in the 1930`s. The FCC accepted their experimental work, conducted at 3 MHz, and used it to set ground system standards for broadcasting in the medium wave band. These standards are still applicable. B.L.&E. did good work.

Another RCA alumnus, E.A. Laport, abstracted some of B.L.&E.`s work in "Radio Antenna Engineering". Figs. 2.17, 2.18, and 2.19 on pages 119 and 120 show field strength as a function of the number of radials. All the Figs. show near perfection with 113 radials, so it seems the FCC rounded up to 120 radials and made it the rule. It`s worked well, giving us good broadcast reception when the earth is dry and sandy or wet and swampy. Laport`s figures show performance with 1/2 and 1/4 the ideal number of radials.

As Walter flattered me, I`ll reciprocate. Get hold of the April 1973 issue of QST. Look on page 35. Walter is pictured there. He is a real good looking fellow!

Best regards, Richard Harrison, KB5WZI

>Tony, I0JX

Dear Tony,

In my opinion, none of the ideas are all that great. However, you surely have noticed that everybody and his brother are doing #1 without even worrying about it. Oh sure, you get the occasional thread here which takes up all three methods to one degree or another. But the vast majority of people using balanced feeders do not have Johnson Matchbox tuners, and they buy tuners with the 4:1 in place, connect it up and it works, after a fashion.

So long as you are running barefoot it's not a problem - nothing gets burned up and you are not losing enough power percentage-wise to ever see a noticeable effect on anything.

Now, to the bigger issue. Do you have a particular reason for formatting your post so that I have to use the horizontal scroll bar to read it. That's terribly inconvenient. No offense, but it's the first time I have seen anything like that.

Cheers!

Thank you, Richard, for considering me for the MAS (mutual admiration society). You are too kind. The issue of QST you referenced contains the first installment of my series of articles, "Another Look At Reflections," which form the first seven chapters of 'Reflections 1 and 2'. Incidentally, the 3rd edition is in the publication stage. I will be posting the release date on my web page at w2du.com.

Back on the subject of radials, unless the FCC has changed the requirements since I was involved, the requirement is for 90 radials. However, most of the AM BC stations I'm familiar with use 120, even tho not required.

Walt, W2DU

Fred and Hamop, Thanks for your help. I think about 82ft or so for the 80 meters, for an inverted V. Basically, the same size as the Alpha Delta DX-CC at 80 meters,

http://www.alphadeltacom.com/dxcc_ii.htm

but that antenna has been on backorder since March. It would be much easier to hang an 82 foot antenna, as opposed to 120 feet. I have an Imax-2000 that I use on 10-12-15-17meters, as well as my CB for the locals. I have an Icom 746 that seems to tune at 17 meters fine with that antenna, but that is about the bandwidth. I have made DX contacts at 17. That antenna is primarily connected to my Grant LT CB for chatting with locals, but I read the review on eham.net, and tried on on 10-12-15-17. The 746 tuner worked perfectly. I was able to make contacts on 10 and 17, but none on 12 and 15, mostly because those bands were dead. So if I can use it on those bands, then I only need a 80-40-20 inverted V.

Hi all

Let me preamble this by saying I am new at this, and need your help. But I am a quick learner!

I have a few specific questions and perhaps you can help. I am trying to troubleshoot a Fm static problem

1) Is the car coax cable lead one or two wires? I am quite sure it is two (one outer (the ground) and one inner wire) but I'll ask to confirm

2) Should a "in-glass" rear winshield antenna be grounded to the car's body? If so, from which end of the coax cable? (see Q 3)

3) Does the expression "grounding the antena" (in the case of a glass mounted antenna) be as simple as soldering a grounding wire from the outside coax lead end that plugs into the HU to a metal ground of the car? Or should it be done closer to the actual antena? SUch as at the junction of the end of the coax and where the antenna starts...

Here is more detail on my problem if this helps: inconsistent FM reception (re: static) with in-glass antenna where I use to get crystal clear reception with old car. However, there is a twist to my problem: I noticed that the coax cable (inner cable) from the HU is not truly connected to the antenna even if it looks like it is. I tested it with a continuity tester and it is not. When I try to connect the inner coax wire directly to the antenna (using a wire and soldering), then I can test it and it is well connected. In other words, the inner wire of the coax makes a continuous circuit from the HU's to the end of the antenna. Yet, I still get some static on some FM station (which is not induced by the engine or the car's electrical systems).

Any suggestion? It is an RSX 2004 (Acura). I changed the HU twice (two models) and the problem persists (same issue with the OEM)

TIA

Danny, I was just perusing the data in the post re the above url and found a typo. In the ground radial data in the line showing 30 radials, the data for 0.4/wl indicating 158 mv/meter should read 185 mv/meter.

I've searched through my files for the one I sent to you containing this data, but I can't find it. I'm assuming you simply copied my data, so it's probably my error, which I'd like to fix in the original. I guess all I can do is ask you to place a correction on that incorrect piece of data to avoid giving the impression that the remaining data may be suspect.

Walt, W2DU

I think you mean the line for 60 radials? Anyway I changed that one to
the 185 figure.

Please double check it for me.

"Coax" is short for "coaxial conductor", i.e. two conductor one outer one inner.

>
> 2) Should a "in-glass" rear winshield antenna be grounded to the
> car's body? If so, from which end of the coax cable? (see Q 3)

That depends on the antenna, but if yes it would almost certainly be the outer conductor. If the antenna has two symmetrical conductors then it should either have a balun (which would be a little gizmo, probably cubical) between the coax and the antenna.

"HU"? Yes, grounding in a car means to the car body.

It may just be a crappy antenna. If you were really determined you
could try a mag-mount external antenna just to see. If it were a
symmetrical antenna I'd build a balun for it (actually I'd probably
think about building a balun for it any time I drove it, but wouldn't
get around to it for years).

For design of 2-frequency trapped dipoles, including traps, download
program TRAPDIP from website below.

First enter in the program the two frequencies and the overall length
you would like the antenna to be.

You have both overlooked the fact that the antenna is also most probably the heating element of the heated (rear?) window. If this is the case then there has to be a d.c. block for the antenna and something to stop the supply cable shorting out the signal. This is usually as small (often cylindrical) device somewhere near and within a short distance of the window connections. If this is faulty it is most likely the cause.

The other question - if it is the heating element then does it completely work? Elements often get minute breaks in them: if the element only partly works then the working part is all you have for an aerial and so you may be suffering from lack of signal.

The most important point however is the nature of the signal/interference. Is it lack of signal - which will give fading and hiss on FM - or is it crackle being produced by the vehicle? If the latter, make sure the earth bonding is good between battery, engine, and chassis. Also make sure it has the right type of spark plugs - most vehicles these days use the type that have a resistor inside them and that is singularly the most effective way of cutting spark interference.

Finally make sure the radio earth is good. If the aerial is disconnected does the radio still work? It is not uncommon for the earth in the main harness to fail and the radio to be earthed through the aerial - which means there will be impedence (i.e. signal resistance) in the supply route which will definitely cause crackle.

SNIPPED to save bandwidth and reading time.

Vinnie, you will find what you need, assuming you are not intimidated by
running a free program on your computer at the site given by Reg earlier.

I quote from his post on your thread:

"Regards from Reg, G4FGQ
For Free Radio Design Software go to
http://www.btinternet.com/~g4fgq.regp"

Look at "TRAPDIP" and "TRAP3" for starters.

Good Luck, HamOp

Grounding an antenna completely defeats its purpose.
Is this also part of a defrosting heating element or such?

> 3) Does the expression "grounding the antena" (in the case of a

> the antenna starts...

The expression "grounding the antenna" is nonsense
in the absense of better colatteral information. If it is
just an antenna (and not part of a heater or something)
then "grounding the antenna" sounds stupid.

What/who/why is "HU"? If this is a part of the circuit
you are working on, you need to reveal the entire situation.
Otherwise, you will get misleading responses based on
guessing from thousands of miles away.

> Here is more detail on my problem if this helps: inconsistent
> FM reception (re: static) with in-glass antenna where I use
> to get crystal clear reception with old car.

In-glass antennas have never been noted for their good
performance. They are only popular because they are
easier for the auto manufacturers (and car washes). Many
people add a proper antenna after-market when they are
stuck with these things.

> However, there is a twist to my problem: I noticed that
> the coax cable (inner cable) from the HU is not truly
> connected to the antenna even if it looks like it is. I tested
> it with a continuity tester and it is not.

If "HU" means Heating Unit or something, it seems likely
that the antenna lead is connected via a capacitor. The cap
would conduct RF voltage while appearing to be an open
circuit at DC (which is what your meter is using.)

If your OK with the possibilty of ruining the phone!
.. you can try to solder a short pigtail of coax to the antenna points you see in the phone. Put a BNC on the end of the pigtail and use this to connect any type of experimental antenna you like.

I dont know about in the Phillipines, but most cell phone operate on several frequency bands, so the antenna is a compromise. If for instance the frequencies are 900mhz and 2400mhz then you need to force the phone to operate on say 900 then attach a properly tuned antanna for 900mhz. Likewise for 2400mhz. A resonant half wave dipole for 900 mhz will be about 33cm (or a quarter wave vertical would be about 16cm tall with radials of 16cm). Directional antennas would be better but they are more critical to build and adjust.

One way to solve your problem might be to sit on the roof to talk, that way you get gain by your height.

Another way might be locate the phone up high, and use a remote headset, and use voice commands to dial out. You still get the benefit of height but can stay inside.

You could put the phone in the focus of a corner reflector or parabolic dish pointed at the cell tower. The phone is the radiator and the dish gives you gain. This is probably the ideal setup if you are stationary in not mobile.

Note: Any time you try to remote the antenna you need a length of coax between the phone and the antenna. At these frequencies, 50ft of even excellent coax (1/2" diameter) will likely completly ruin any gain the antenna may give you. You would only be eliminating some sources of noise by getting up away from the house. Directional antennas give +gain and the neccessary coax gives -gain but hopefully not as much, so you come out ahead.

Has it taken 70 years for the old wives of the FCC to return to Earth,
disregarding B.L & E who forgot to measure ground conductivity, not to
mention permittivity, and think again about economics?

The only stations that the FCC is concerned about is commercial.
And the reason they stick with the standard number is for stability
and getting the max bang for buck, and an easily expected
performance level. Buying a load of wire will beat using more
transmitter power over the long run. If they use 120 radials,
they know they will be getting close to maximum performance.
If they don't, it's a crap shoot. 120 radials *will* outperform
16 of them. There is no question, unless they are over sea
water. I'm not saying hams have to run that many. In fact, I
think 60 will do for most, except the most hard core for good
results. Even less for the more casual user.
But I have no problems with the FCC wanting a certain level
of performance for commercial stations. I have no problems
seeing why they do it either. Wire is cheap compared to
todays level of monthly light bill. With some stations, the radials,
or lack of , in certain directions gives them a controlable
pattern with no surprises in f/s over a period of time
with changing ground conditions. The main thing is
stability of performance over periods of time. Or thats
my take anyway.

greeting,

can a passive repeater will work on my cp. my plan is this: to build a yagi antenna for 900mhz outside and another antenna, a corner reflector. is pointing my corner reflector to the yagi will work in improving the recepcion or should i need a coax cable connected to the reflector antenna from the yagi? any advise would be appreciated...

thanks,

ian

238. Need help with NEC modeling

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-07 02:16:23 UTC
From: W2RAC <w2racNOSPAM@cfl.rr.com>
Message-ID: <b6jsh19a8vpng08i4dtt0rm4ds26ckl51a@4ax.com>
Source record: 70935

PLEASE, I need help.
If anyone can run the numbers,
I have tried Quick Yagi with little success.
I have a pair of the OLDER Hy-Gain 2m antenna's. There design was a
200ohm Hairpin match (to 50ohm) with the reflector and
directors INSULATED from the boom.

Current model for the last 10+ years is the elements are not insulated
from the boom.

I want to respace the elements, possilbing cutting down as it is
easier than lenghting them, to get the best results for gain/pattern

I am only going to use them on 2M SSB with a center freq of 144.250

Here are the measurments.
14' boom
El Lgth Space
D6 34.62500 32.25
D5 35.00000 26.75
D4 35.12500 25.75
D3 35.12500 28.25
D2 35.25000 22.25
D1 35.50000 12.75
Driven 32.75000 16.75
Ref 44.37500 1.75

Notes. Measured in Inches. Reflector is mounted 1.75 inch from end of
boom, D6 is 1.5 inch from end of boom. All Elements are INSULATED on
top of the boom. If needbe I can remove 1 director as the insulator
need replacing.

All,

A fundamental basic question, which is the primary purpose of radials:

1. is it to create a ground, that is a as close as possible to zero ohm virtual reference for the 'real' vertical half of the dipole?

2. Or are they to create a real resonant half of a dipole?

If it is the first then what does the 'efficiency' curve look like for a shortened, loaded, vertical? That is if the vertical element is loaded to resonate at 1/5 of a half wave length what does the ground resistance profile look like for 120 radials at various lengths of 1/20 wave, 1/10 wave and 1/5 wave?

The question I am really driving at is if mesh is layed down at 100% coverage about what fraction of a wave length needs to be covered to create a 2.5, 5, and 10 ohm equivalent ground for the vertical above?

In the paragraph above is the mesh simulating a ground or is it fact operating as a ground.

Thanks,
Dan

And one other easy thing that definately helps on VHF/UHF, is cleaning the aluminum elements. I use scotchbrite pads with aluminum cleaner. As I remember Brasso maight be a substitute. Someone correct me if I'm wrong there. If the cleaners aren't available, just the pads plus light detergent followed by a good rinse will do a lot to clean up the skin of the element.

At VHF and higher there are eventually problems from corrosion with uninsulated elements on conductive booms unless the elements are welded to the boom. At HF, actually by 6m, the problems are ignorable, because the boom diameter is not a significant fraction of a wavelength.

So 6m and down, whatever you want is fine, 2m and up, uninsulated is better for a long lived beam.

And that goes for all elements.

It would be helpful (necessary) to know the element diameters and the
spacing from -one- reference point.

There are many "modern" designs published in the literature.
Boom correction factors for insulated/non-insulated elements are all
available on the web.

Practically everything you need to know can be found by starting here:

http://www.ifwtech.co.uk/g3sek/diy-yagi/

One of the links:

http://www.k7mem.150m.com/Electronic_Notebook/antennas/yagi_vhf.html

might be especially helpful to you.

In passive repeaters, you connect the 2 antennas with some transmission line (like coax or twinlead or ladder line).
Point one antenna to the station you want to receive, and point the other antenna to your location.
They make these things to fit on cars for better cell phnone reception - but they are not directional antennas.

Sounds like a loose connection - possibly in the power supply (DC voltage).
Does the static also happen on the AM band ?
If so, the loose connection may be in the power supplying the radio.
If positive side checks out ok - don't forget to check out the ground side - all the way back to the battery.
I had a similar problem with an old buick once, and fixed it (after much troubleshooting with a multimeter) by running a wire from the negative side of the battery to a screw on the body - The lights stopped blinking - the radio static cleared up - and all was well in the world.

248. Reflector on a quad - Capacitor use?

Hi Blue, If you will notice the sizes are different for an unloaded, inductive and capacitive loaded reflector. The current distribution in the 3 examples will be slightly different, resulting in different gain/rejection. I think the idea is to make all three reflectors perform the same, but as you see, there is a slight difference.
If you have a modelling program, such as EZNEC, you can model a quad. Then change the reflector length and note the change in current distribution, gain, and F/B. You can also add loads and see the changes.

That's because there's no power for the old tube type rig.

253. Advice on building a 6 meter vertical antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-07 13:44:44 UTC
From: pinpassion <mjdrum@comcast.net>
Message-ID: <1126100684.670634.172990@f14g2000cwb.googlegroups.com>
Source record: 70950

Hi Gang,

I'm building my first 6 meter vertical antenna
for repeater use. I already have a 6 meter beam
for SSB DX use. (Cushcraft 5 element)

I'm using the plans from G3JVL for a 5/8 wave
aluminum antenna. I have the tubing from Texas
Towers (extruded aluminum) designed to fit in
to each other, so this should make a perfect
antenna when I get it cut to size. For those
not familiar with the G3JVL antenna, here is
a link:

http://www.hamuniverse.com/6metervertical.html

The advice I need is how should I protect the
antenna prior to putting it on the roof? Is there
a spray I should use to resist rust, or something
I should use when I connect the sections to help
maintain a good connection and prevent oxidation?
I suppose this might have the added benefit of making
the antenna easier to disassemble.

I was planning on using stainless hardware to assemble
the sections. I was initially thinking of using a
stainless hose clamp, but I was advised to drill a hole
through the sections and use a bolt and nut as that is
more reliable.

This is my fist shot at a homebrew, so any advice is
appreciated.

Thanks,

Mike N2QAC

254. Dummy Load experience?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-07 14:02:07 UTC
From: CD <mr.whatever@gmail.com>
Message-ID: <1126098596.599662.122930@o13g2000cwo.googlegroups.com>
Source record: 70951

Hi all,

I'm curious about dummy loads. I read that ideally dummy loads convert RF energy into heat, but I'm sure in the real world, there will still be a small amount RF energy transmitted.

My friend tried using a dummy load on a 300W transmitter. He was only running it for a few mins at the VHF range, but he was picking up a signal 100 ft away. Is that typical?

What's your experience on dummy loads? Were you able to pick up a signal, as well, with this type of distance?

I don't know much about dummy loads, but I think that 100ft is just a tad bit too far, no?

MK,

How satisfying it is to read your message, written in plain, easy to understand, well-punctuated English, without any undeciferable coded abbreviations.

I agree with what you say although I am unfamiliar with exactly how the FCC fits into the scheme of things.

Amateurs and commercial broadcasters have a common fundamental requirement. There is a service area to be covered with a given field strength. Depending on frequency, requirements then diverge. But the design methods used to satisfy requirements are all confined (or should be) to the principles of engineering economics. Inevitably, the Dollar, Pound, Frank, Mark, Rouble and the Yen rule the roost.

Both commercial broadcasters and amateurs do a cost-befit analysis. The broadcaster takes into account the revenue acruing from selling the service. The amateur, whether he likes it or not, has to ask himself what the satisfaction of using the station is worth.

Amateurs' bank accounts are not unlimited.

Field strength at the limits of the service area depends on the power efficiency of the radiating system. If engineering economics dictate use of a set of buried ground radials then the peformance of the ground radials must be included. Considering the system as a whole, it may be economical NOT to achieve the maximum possible radiating efficiency. Indeed, the maximum is seldom the target.

If there is an economical choice in the matter, once the location of the station is decided, everybody agrees that efficiency depends on soil resistivity at the site. To estimate efficiency it is necessary, at the very least, to make a guess at soil resistivity. Perhaps just by looking at the type of weeds growing in it. Or it can be measured.

Depending on how far it enters into station economics, it is possible to numerically estimate efficiency from the number and length of radials AND FROM SOIL RESISTIVITY.

B.L & E and the FCC don't enter into it.

Reg.

Even with a perfect dummy load you'd still get some leakage from your transmitter and cabling -- I generally expect that if I run into a dummy load I'm going to peg the S meter of any receivers that are on-frequency and in the room.

So picking up the signal 100ft away doesn't surprise me.

Message-ID: <18566-431EFC60-34@storefull-3258.bay.webtv.net>
Source record: 70954

Ian wrote:
"Can a passive repeater work on my cell phone?"

Whenever you use a passive repeater in a path, you split the path in two. The attenuation is greatest in the first few feet of the path. After the first few feet, signal strength declines only about 6 dB every time distance from an antenna doubles. The much greater loss of two paths (add about 22 dB) versus the loss in a single path is the reason passive repeaters are unpopular in most cases.

If very high gain antennas can be used with a passive repeater, its high loss can be overcome. This is unlikely in a cell phone application. Microwave systems use passive repeaters in unusual cases such as periscope antennas and mountain top billboard reflectors that are very large and close spaced.

If one antenna of a back to back pair can "see" one end of a radio path, and the other antenna can "see" the other end, the pair may make an effective repeater, but will have much loss.

Best regards, Richard Harrison, KB5WZI

The best I can make of this isn't much improvement since the elements
for the most part are too short.

By cutting the reflector down to 41.5" there is some marginal
improvement in gain and F/B.

The existing design has G = 9.5 and F/B ~9.0.

With a 41.5" reflector, G ~ 10 and F/B ~ 10.3

If you could lengthen D1 and D2 to 37.5" and 36" respectively, then G
= 11.0 and F/B ~ 16, with a decent pattern.

This will be accompanied by a big lowering of feedpoint resistance,
which is to be expected.

Sorry to disagree, Reg, but it appears you're overlooking an important point--the difference between the efficiency of the radiating system itself, versus the efficiency of the ground area external to the radiating system.

BL&E shows that when 90 - 120 (actually 113) radials of 0,4 w/l form the ground system for a 1/4 wl radiator, the efficiency is 98.7% efficient, REGARDLESS OF THE SOIL RESISTIVITY UNDER THE RADIALS. This is shown by obtaining the field strength of 192 mv/meter at 1 mile for 1000 watts delivered to the antenna under the conditions described above, compared to 194.5 mv/meter with a perfect ground having an efficiency of 100%

It is only the soil resistivity of the ground external to the radial system that determines the field stength external to the radial system. Consequently, the soil resistivity (or conductivity, if you like) is significant only in the areas external to the radial system.

There is the guy who got a Worked all Continents using only a light
bulb as his antenna. (And basically it's just a dummy load, though
the resistance varies and so it doesn't make a very good dummy load,
though it shouldn't make a better antenna than a good dummy load. Was
that sentence long enough?)

The leakage of your rig and the feed lines is signifigant. And of
course, the dummy load itself will radiate a little bit too. You may
have a hard time getting a WAC, but certainly the signal is there and
can be picked up by those close. It's also why it's a good idea to ID
yourself and such even when transmitting into a dummy load.

Mike;

The first advice to protect your new antenna prior to mounting it is to insure that nothing is allowed to fall on or against it while it is in your shop. This is very detrimental to the final look of the antenna. ;^). Seriously though being made of aluminum it will not rust. It will

lightly oxidize but this is a natural action as aluminum is very reactive with oxygen. If you are in a salty environment you might lightly spay paint the aluminum with either a color paint or a clear finish otherwise you really do not have to worry about the metal. Just be sure that your paint does not have any metal in it.
One thing you might want to consider is coating the joints between two pieces of metal with a conductive grease. You should be able to find that at a Radio Shack or other electrical supply house. Using a nut and bolt to hold sections of tubing together is a very good idea, just be careful when tightening the nut not to crush the tubing.

Good luck;

If I might insert my comments. I whole heartedly agree with the other responses. A dummy load will radiate and using light bulbs as a dummy load will work.

However, they will radiate emf as well as light. One of my mother's cousins, Arnold W2OVP SK, received his first ham license on something like 8DEC1941, if you are a student of history you know what happened next. Radio Silence until after August 1945. Anyway one night he was practicing his CW into a bank of light bulbs at his home in Buffalo, NY. He received a phone call from one of his friends on the other side of town that his code sounded good. Suffice it to say that he shutdown and did not do that again. So yes a dummy load will radiate, just not very efficiently.

There is no such thing as "creating a ground". As for a "virtual reference", you can declare any point on any conductor a "reference" and for that matter "ground" that you wish.

> 2. Or are they to create a real resonant half of a dipole?

There's no need to try to make a dipole. If the radials are on or very near the ground, their sole purpose is to reduce the amount of loss due to current returning to the base of the antenna. The current entering the antenna at the base equals the current flowing into the source through the ground. This ground current results in I^2 * R loss; radials reduce the R and therefore the loss.

In the case of a "ground plane" antenna with highly elevated radials, the radials provide a path for the base current to flow (again, current out of the source -- into the antenna -- has to equal the current into it -- from the radials). Because of the physical configuration, it's sometimes more convenient to build an antenna this way instead of making a dipole. The radials radiate very little, and the vertical section radiates twice as much per unit length as a dipole, resulting in the same overall gain and pattern.

> If it is the first then what does the 'efficiency' curve look like for a

> wave and 1/5 wave?

The answer to this depends on the ground conductivity and frequency. But the radiation resistance of the shortened antenna will be less than that of a full-height one. Therefore, if the ground resistance is fixed and determined by the ground system (not completely true -- it does depend some on the antenna height -- but close enough for discussion), the efficiency of the short antenna will be less than for a full-height one. I recommend finding and reading "The W2FMI Ground-Mounted Short Vertical", by Jerry Sevick, W2FMI in March 1973 QST. He built several antennas very much like you describe and made extensive measurements.

>
> The question I am really driving at is if mesh is layed down at 100%

Sorry, I don't know the answer to that one right off the bat. It could be determined with NEC-4 modeling, but I don't have time to do that. I suggest that you locate a copy of Brown, Lewis, and Epstein's paper "Ground Systems as a Factor in Antenna Efficiency", now posted on the web. You should be able to get a fairly good idea from their measurements of 113-radial systems.

>
> In the paragraph above is the mesh simulating a ground or is it fact
> operating as a ground.

I really don't know what "simulating a ground" and "operating as a ground" means. But the radial field doesn't act like either real Earth or a perfect infinite plane, if that's what you mean. If sufficiently fine, a mesh will act like a solid conductor the size of the mesh.

A friend of mine and I used to do 'code practice' on 40M with our rigs cranked down to approx 20 watts each -- using Heathkit Cantennas at both ends. S-9 sigs both ways. We were 5 blocks apart.

As well, once a week we used to (attempt to) check into a distant (180 miles) 2M SSB. While waiting for net control (and the rest of the net) to point in our compass direction (220 degrees - approx 35 past the hour), we'd chat back and forth - again switched into the Cantennas. And, again, S-9+ sigs both ways.

It's more a testament to the quality of good receivers now-a-days -- than the leakiness of a dummy load. Look over what the QRP and QRPp folks are doing - with their "Millions of Miles Per Watt" records, and you'll realize (if you haven't already) than you can happily 'do' amateur radio with Not Much Watts.

If that 300 W was all radiated from a matched 1/2-wave dipole, it would generate a free-space, maximum field of about 4 volts per meter at a distance of 100 feet.

If the sum of cabinet, cable and dummy load radiation was 80 dB below that, the maximum free-space field at 100 feet would be about 400 microvolts per meter -- a very healthy signal.

Walt, just what is it you cannot agree with? You appear to be making
an argument where none exists.

It is obvious there must be a distant point beyond which a large
number of radials will approach 100% efficiency regardless of ground
resistivity. B.L & E and the FCC arbitraliry decided on
1/2-wavelength and 120. Both nice round figures.

I'm sorrry to say you appear unable to agree that for the remaining 99.9% of all possible cases, ie., for cases less than 1/2-wavelength and fewer than 120 radials, that GROUND RESISTIVITY in the immediate vicinity of the antenna DOES HAVE A SIGNIFICANT EFFECT ON EFFICIENCY and it cannot be disregarded.

My only criticism of B.L & E is that they forgot to measure soil resistivity before leaving the site. And apparently, nobody has ever bothered to go back and do it for them.

The only mention of their work occurs on this newsgroup. When laying radials, 99% of amateurs forget B.L & E (if they have ever heard of them) and the magic number of 120.

Hasan Schiers has recently given a blow-by-blow account of a sensible way to lay a set of radials with the reasoning behind it.

Reg.

Reg, G4FGQ wrote:
"The broadcaster takes into account the revenue accruing from selling the service."

Yes, and he takes into account the ease of compliance with FCC Riles in the USA.

Although 90 radials is a minimum requirement for the U.S. AM broadcaster, here is the rule quoted by John Edward Cunningham in his 1977 "The Complete Broadcast Antenna Handbook", from page 311:

"The current FCC Rules specify that the radials should be at least 1/4 wavelength long and that there should be as many as practicable, but in no case less than 90. The Rules add that a system of 120 radials spaced every 3-degrees and extending 0.35-0.4 wavelength from the tower is considered an excellent ground system. In addition, a square ground screen 24 or 48 on a side is often provided at the base of the tower, particularly when the tower height is such as to cause a high voltage.

Whenever a less than optimum ground system is used, the FCC requires a complete field-intensity survey to establish that the effective field at one mile meets minimum requirements."

Best regards, Richard Harrison, KB5WZI

My dummy load is 100% enclosed in oil AND a 1 gallon can. This is pretty tight. I estimate leakage at around -120 to - 130 dB.

I run about 10 to 11 feet of coax from my transmitter to the low pass filter to the tuner to the antenna switch to the dummy load. The coax is good quality 9913. BUT, it uses a woven copper braid as the overbraid. The braid has a leakage impedance of typically 0.020 + jw10^-8 ohms. The inductive term means that the little holes in the braid 'LEAK' rf. At VHF the coax isolation could be -60 to -80 dB. So, a 100 watt signal could leak between 10 and 100 microwatts. If you have a cell phone that power level is close to your cell phone's power output. Your receiver will detect a signal 1 one millioneth as strong.

What would you suggest as a method of measuring the RF ground resistivity to a depth of 17 - 100 feet (3 skin depths at 3 MHz for the range of likely resistivities)? Assuming it's very likely that the resistivity would be quite different at different depths within that range, how should they have used that information? How would you use that information if someone "bothered to go back and do it for them"?

Reg, all signs point to your being seriously in need of a holiday. How about a little trip to New Jersey to show us Yanks how it should have been done? For less than the price of a couple of bottles of decent wine, you can buy everything you'll need -- bucket, pocket DVM, trowel -- right there, so you won't even have to carry any equipment with you.

Look at the way the Beam is heald together and use that method. The split
ends and the SS hose clamps. Use AL or SS for everything you can. If you
want to you can shine up the elements where they mate and use some pentrox
on them you can get from an electrical supply place. Maybe evens Lowes.

Mike:

One thing that no one will tell you is why manufacturers use plated hardware which rusts instead of stainless. Cost? No. Stainless will not stay tight, while plated hardware will rust up and then never loosen. So, if you use stainless, it is highly desirable to use Nylon insert locknuts or else carefully double nut everything, and add Loctite before assembly. It is no fun finding another piece of the antenna at the bottom of the tower every day after the wind blows a while.

George, I wonder if you tried lubricating the ss parts before
assembly.

Stainess threaded parts are well known for galling, and can bind
before properly tensioning the fastener. It is a widely debated topic,
but common advice is to lubricate the parts. Google for debate on what
to use (wax, WD40, grease, moly etc)

My experience is that stainless threads should be lubricated whenever
used with nyloc nuts to reduce heat damage and galling of the nyloc
insert. Marine grease seems to work fine, and it doesn't seem to
unduly upset the prevailing torgue characteristics.

Mike, ss hoseclamps on telescoping tubes with split ends seems to work
fine. Put a bit of marine grease on the worm in the hoseclamp. I think
you are less likely to crush the tube than through-bolting it.
Remember that the joint is going to flex to some extent. A little bit
of corrosion inhibitor in the slip joint will help maintain a good
connnection through life... depends on the environment as to the
necessity to to this.

FWIW.

Owen

Bob -

If you wish to clean the aluminum - lye (NaOH) is often used - however this is a caustic agent - and usual precautions should be used if you use this approach. There are also aluminum cleaners available at your local auto supply stores.

Although some amateur use steel wool pads -- this can leave steel slivers on the aluminum tubing that can oxidize (rust) - I refer non metallic scrubbing pads if you need some elbow grease.

Scothbrite pads seem to work great for cleaning off oxidation from
aluminum...when reassembling the joints, one can use penetrox (as
someone else mentioned) or alnox, both should be available at electrical
supply outlets.

Further to Richards comments

You can also model a passive repeater reasonably easily. With a propagation modelling pgm (eg Radio Mobile, UKWTools etc) find out what the receive signal level will be at the "repeater", then do a coverage study with that signal from the repeater site.

In my experience the signals are very low and not often worth it. I was however involved in a setup to get signal on 400MHz into a railway cutting from a TX site only 1800 metres away. The measured signal in the cutting was about -107dBm but with the passive setup that came up to about -87dBm. In this case the cutting was on the side of a mountain (ie no other usable reflections) and the useful distance from the passive repeater was only about 200 metres. The repeater was a 14dBi yagi pointed at the distant TX site coax connected to a 8dBi yagi pointed down the cutting.

Cheers Bob W5/VK2YQA

Glancing at Fig. 2.17 on page 119 of Laport`s "Radio Antenna Engineering" shows that BL&E would agree.

1000 watts into a 90-degree vertical with 16 radials will produce about 160 mv/m at one mile. Perfection is only about 190 mv/m. 85% should be close enough to perfection, unless you are a broadcaster or the FCC enforcing its rules on a broadcaster.

Best regards, Richard Harrison, KB5WZI

==========

I am reminded of the military engineer who was dispatched by Napolion, an engineer himself, in connection with standardisation of the Metre, to measure the distance between the Earth's Equator and the North Pole.

Measurements began, but the further the engineer departed from his beautiful lady friend in Paris the more difficult it became to make progress along the route. Eventually, he couldn't withstand the mental and physical stress. He returned to her Parisian boudoir and resorted to cooking the books in what time he had to spare.

So, the International Standard of Length, The Metre, held in Paris, France, carefully guarded by the German occupying forces during WW2, may or may not be equal to 39.37 English inches.

Actually, the most fundamental physical measurement standard is the Mass of the Standard Kilogram on which everything else depends. But it is quite an arbitrary quantity.

I have just finished a bottle of Blossom Hill, Californian, white wine. Makes a pleasant change to arguing about what 'amateurs' BL&E might, or might not have done before leaving the site.

I hate to say this, Reg, but calling BL&E 'amateurs' is insulting to
me. I knew them well, and worked with B and E in the RCA Laboratories
antenna lab, and they are anything but 'amateurs'. I think you
finished off the Blossom Hill to rapidly.

Perhaps you should take a look at the long list of IRE articles
published by Dr. G.H. Brown, reporting his work that shaped the
present design of all AM BC antennas. Did you ever wonder what
happened to the diamond-shaped AM towers? And why the AM towers
constructed since 1940 have a uniform cross section?

And did you know that Dr. Brown gave John Kraus, W8JK, the idea of
close spaced elements that culminated in the 'W8JK Beam' antenna?

L, (Bob Lewis) is also a fine engineer, although he is also a ham,
W2EBS.

If your harmonics are causing TVI problems, an MFJ-704 could keep your neighbors happy while you have fun hamming.
MFJ's Super Low Pass filter simply plugs between your rig and antenna. It suppresses TVI, RFI, telephone and other interference by reducing unwanted harmonics going to your antenna. At the same time your HF signal passes on through with low loss so you can snag rare DX.
Nine Chebyshev poles, MFJ's exclusive TeflonDielectric Technology capacitors, Hi-Q inductors, ground plane shielding and an RF tight cabinet give you excellent TVI and RFI protection. (Right from the MFJ flier.) Instructions & box included. ONLY $19.95 plus $8.95 shipping and insurance. First e-mail gets it! 73, Bill - WA8MEA - ars_wa8mea@netzero.com - http://HamRadioFun.com

Arc welding rods are usually coated. Gas welding rods are not, and could be
brass, steel etc.

==========
Because the loading capacitor requires a tad bit greater length of the loaded element which, for the same frequency, slightly changes the radiation pattern.

When a loading coil is used the element is a tad bit shorter and, combined with the small loss in the loading coil, it has the opposite effect.

Owen:

We've had this discussion before, and I must be using better quality stainless hardware than you have used. In the dozens of pounds of stainless from 0-80 up to 5/8" I have installed in the last 40 years, I could not specify when the last one galled if I had to. And I take lots of them apart, in addition to those which I expect to last forever. OTOH, somewhere around 40 years ago when I first started using stainless, I found plenty of it on the ground under a month old installation until I wised up about the fact that lock washers, even split ring style, were not enough to hold under constant vibration. And especially so on tubing where the tubing collapses before the lockwasher will bite into the nut.

Source record: 70901

Hi Ian

The "back to back" antennas of the passive repeater are simply joined by a transmission cable that suits the antennas. ie If they are 50 ohm antennas use 50 ohm coax. Think of one of the antennas as a source of signal and the other as a load (although they work in both directions) hence the connection is simple.

So the system is;

- The passive repeater consisting of two antennas. One (yagi?) pointed at the cell tower the other (whatever it is) pointing at the place where you will be using the cellphone. If you are moving around a bit with the phone you may wish to use a reasonably wide beamwidth antenna rather than something too directive.

- If there still isnt enough signal you could mount another external antenna on the cellphone itself pointed at the passive repeayter antenna.

- Design of the antennas will also include selction of coax etc connection. You could equally as well built antenas with 300 ohm impedence and join with them 300m ohm ribbon. Are you building your own or buying antennas off the shelf? I'd actually suggest some corner reflectors as they are not as critical as long yagi's and have a more useful/wider bandwidth coverage. mr Cebik (http://www.cebik.com)has some corner reflector designs you may be able to scale to 900Mhz.

Cheers Bob

Traditional is steel (i.e. coat-hanger wire :-)

In reality, it makes no difference except mechanically.

> What thickness or size.

It is a mechanical issue. What makes it self-supporting?
Electrically it is of no significance.

> Lenght?

Well, the middle of the FM broadcast band is ~98MHz
and 1/4 wavelength is ~28.5 inches.

306. Ferrite bar antenna for car radio

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-09 05:07:54 UTC
From: wrongaddress@att.net
Message-ID: <1126242474.864784.197660@g14g2000cwa.googlegroups.com>
Source record: 70903

Any idea how to couple a ferrite loopstick antenna
to a car radio input for AM reception?

I experimeted using a 6 inch loopstick and tunning cap
with reasonable results, but I'm wondering what the
best approach is.

I connected one side of the tuned circuit to the
chassis of the radio, and other side to the antenna
input. But the tuning is very broad and I don't get
a very sharp peak when adjusting the capacitor.

It seems the car radio input is very high impedance
and doesn't load the loopstick much.

Would another winding on the loopstick of longer
length work better?

Would a JFET amplifier improve the operation?

-Bill

I've noted that the usual rhetoric from the "Ham Radio Will Never Get Through When Anything Fails" crowd, specifically from the patriarch of the Feeble Five, Lennie "No Guts" Anderson, has waned in the face of MAJOR media stories in all facets of "the press" that have lauded Amateur Radio.

Even the snide remarks of some lame slime from Motorola has been laid waste.

Source record: 70906

Gentlemen,

I am attempting to identify the tower manufacture of the tower pictured at: http://www.ppinyot.com/antenna.htm. I would like to properly design a base for it given the manufacturers specs plus perhaps pick up additional sections.

The tower seems to be of a stamped steel design (not tubular) with stamped steel cross members. It has been well maintained by the silent key's son. I gather it is about 10 to 15 years old. There is an unpainted ladder chained to one side for storage. Please do not confuse this as part of the tower.

Also if you happen to recognize the beam please Identify it too.

Unfortunately some one discarded all the paper work not knowing it's value.

Thanks Paul

310. K!MAN Has a Case ...

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-09 12:21:14 UTC
From: Morris <Sherins@bellsouth.net>
Message-ID: <1126268474.457608.134880@g47g2000cwa.googlegroups.com>
Source record: 70907

He's crossed the line numerous times: doing foreign policy, defaming Riley Hollingsworth, going commercial. But he has a case.

When Ervin Duggan was FCC Chief Commissioner in the 80s, Baxter received two NALs similar to the present. Dutifully, he spent a great deal of time on his response, serving same on the FCC by regular mail. When the mail was "lost," Baxter resorted to Federal Express with no better result.

So, here was an agency, pre-Hollingsworth, that had issed two NALs and had purposely sandbagged K1MAN's answer -- with good reason.

In his answer, Baxter cited two documents of probative value. One was a letter to Kenneth Black of Ulmerton, UK, responding to his complaint, that gave K1MAN's operation a clean bill of health, equating it to W1AW bulletins. It was signed by Robert McNamara, Chief of the FCC, then-Private Radio Bureau.

The other was a declaratory order on the subject of the length of Information Bulletins with a footnote that referred to W1AW published schedules. The essence of the order was, information bulletins cannot be proscribed by time limits since they are so varied. Rightly or wrongly, Baxter has drawn his authority to come on when he does from that Order's footnote.

Small wonder the FCC disregarded K1MAN's answer, which essentially held that the issue of the NALs had already been settled in his favor. In legal argot, res judicata.

Though most hams, including myself, want to march Baxter right out of this service, justice dictates something else. The FCC, it seems to this commentator, has the burden of first addressing its previous NALs of the 80s which were never resolved.

An agency of government simply cannot throw a flurry of similar charges at a citizen, selectively unresponsive to those that can be defended, while arbitrarily limiting its attention to subsequent charges. Certainly, to the extent the previous NALs are similar, the legal principle of collaterol estoppel comes into play in Baxter's behalf.

I don't like what Baxter does any more than you. Indeed, I think he lost his way years ago. But if we're to have justice for all in these United States, then we must afford K1MAN justice. Let's not throw out the baby with the bath water.

Dear Paul (KB3LZP):

Even for free, the tower and antenna appear to me to be too expensive.
You will have to pay rigging twice - once to take the tower apart (assuming
that can be done without damage) and again to erect the tower. The
connection bolts are likely to need to be replaced - especially at the
connection to the foundation.

In the end, you will have (at best) a short tower of dubious safety with
an obsolete antenna that does not cover 18 and 24 MHz bands. You will have
a better, and more safe, result to erect a new, taller tower with known
safety factors and an antenna designed to cover the present bands (above 14
MHz).

As the old Scot has said: even for free, somethings are too expensive.

73, Mac N8TT

313. Efficiency of Power Amplifiers

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-09 15:13:13 UTC
From: Cecil Moore <mycall@arrl.net>
Message-ID: <1126279011_1471@spool6-east.superfeed.net>
Source record: 70910

The latest QEX has an article by k9la: "The Impact of Load SWR
on the Efficiency of Power Amplifiers". The amplifier is designed
to drive a 50 ohm load and simulated measurements were made for
8 reflection coefficients of 0.333 with phase angles in 45 degree
increments.

One thing I don't understand. When driving a 100 ohm load, the
drain current is 33 amps and the efficiency is 62%. When driving
a 25 ohm load, the drain current is 12 amps and the efficiency
is 83%.

The amp is a Class E/F design from Jan/Feb 2004 QEX. Why would
the drain current fall when the load is decreased from 100 ohms
to 25 ohms?

The output filter of an amplifier can act like a 1/4 wave (or 3/4 wave) transmission line, so a high impedance at the antenna terminal would look like a low impedance at the final, and visa-versa. This extends to the time-delay properties: older oscilloscopes with time delay used long L/C filters operated way below cutoff to simulate even longer stretches of transmission lines.

In fact, a filter that looks like this

```
___
--------o---UUU---o--------
| |
--- ---
--- ---
| |
| |
=== ===
GND GND
created by Andyï¿½s ASCII-Circuit v1.24.140803 Beta www.tech-chat.de
```

with all reactances equal to the design impedance (say 50 ohms) at the design frequency is _called_ a 1/4-wave filter. Put two of them together and you get a 1/2 wave filter:

```
___ ___
--------o---UUU---o---UUU---o------
| | |
--- --- ---
C --- 2C --- C ---
| | |
```

```
| | |
=== === ===
GND GND GND
created by Andyï¿½s ASCII-Circuit v1.24.140803 Beta www.tech-chat.de
```

Stick on another section and it'll act like a 3/4 wave line, etc.

I should have described the output circuitry. It's a push-pull
LC tank circuit with DC supplied by the coil center-tap. The
output is just a link coupler. The low-pass filter is a single
series L and single C to ground.

No waviering here. The ARS proides usefull service, mostly in keeping
H&W stuff off the plate of those with better things to do.

It does not properly replace the system used by the cops as witness the
keystone cops bummbling we see and here about

the ARS is not saving the day or saving civilation, it is hellp people
lessen the impact of the disaster, what I have been saying all along

you would be better to place a lightning arrestor at the tower (and ground the tower as well) and perhaps 1 or 2 along the coax to your house (all ground rodded). This method is referred to as "defense in depth".

its how I did it with an old CB setup on a large lot 20 years ago. saved a lot of heartache (though I did have to replace coax a bit more often).

Based on the cited NALs and logic the conclusion can be reasonably drawn
that we have 600,000 licensees who have a 'right' to follow K1MANs
example. Restated: CHAOS and Anarchy abound.

I don't believe that is the intent of the amateur radio 'PRIVILEGE'.

How has the QL changed as a function of load? How has the power output changed from 110 to 25 ohms load? Have you calculated the effective load lines for the amplifiers?

We need a lot more information.

I don't subscribe to QEX so I don't have the circuit available.

Methinks a very strongly worded letter from ARRL to the head honcho at
Motorola might be a good idea.

73
and special kudos to all those volunteers.

The original Windom *was* an intentionally off center fed multi-band antenna. Anybody have info on the Windom from the 40's 40's. Dad used one, but I don't know what he did.

Ahhh! You stole' my thunder. Coax typically only has 60-80 dB isolation at
best and that is if it is made well and connectors are on well. Before it
even gets to the coax connector of the radio, there'll be some radiation.

>Amateur Radio.

"Patriarch?!?" :-) Not I, never having met in-person any of
those against the mighty warrior of "seven hostile actions,"
Dudly the Unconquerable...aka Dudly the Unhumbleable. :-)

"Waned?!?" :-) Life goes on 2000 miles away from the Katrina
hurricane devastation.

Ahem...the "MAJOR media" are reporting as much as possible about
the Gulf Coast damage. That is of considerable quantity.

Reporters, journalists, telecasters are all on-the-scene covering
an enormous area of extensive damage with many, many "human
interest" stories appearing. Anybody with a working TV set can
see/hear that; anybody with a working BC receiver can hear that.
Anyone able to read a major newspaper can read that. Anyone with
a working PC and an Internet connection can find that out.

What Dudly is doing in here is just ordinary FLAMING because he
is obsessed with FIGHTING. [wannabe-warriors get that way...]
Yes, stories have been filed with newsservices on amateur radio
doing their part in aiding the relief effort, but are those
relief actions of amateurs of any notable effect on society as
a whole? Health and welfare messages have not been shown to "save
lives" on any large scale...a large scale such as a MILLION

displaced and homeless citizens in the Gulf states affected by Katrina. Perhaps nearer to two MILLION people displace, homeless, or dead when the tallies on human lives is more complete. The scale of damage is too vast, too shattering to millions more.

Thousands and thousands of volunteers and paid workers are very busy at the moment, doing many things of DIRECT AID to the homeless and displaced, all WITHOUT any direct "need" to do radio communications about "health and welfare messages." That's important work. MOST (very nearly all) of that work can be done WITHOUT a lot of radio communications. Coordination of effort does require communications of some kind, but the "coordination" of ALL agencies, paid and volunteer, were simply NOT prepared to deal with the magnitude of damage and destruction that happened. That includes amateur radio, folks, whether it smarts your little egos or not. Did anyone really think that a few dozen hams could really make a "difference" by sending health and welfare messages from millions to other millions? No doubt the self-proclaimed amateur patriots far from the disaster scene were happy as larks to see the tiniest factoid of their Great Help to the victims of hurricane Katrina. They have waved their banners, cheered as loudly (and abusively) as possible, pinned invisible medals of valor to their equally invisible uniforms of service they wear in the newsgroups.

But, things eventually get sorted out and the REAL coordinators can organize things, start to do the REAL rescue work such as pumping out all those millions of acre-feet of flood water, finding shelter and food and sanitation for a million or more displaced and homeless people, trying to restore a large city and many smaller cities along the Gulf. The REAL health workers have been on the scene, pulling out bodies of the dead, measuring the countryside for disease, taking steps to control insect-borne diseases, preparing for the epidemics that might ravage the survivors. REAL work, down on the nitty-gritty level, done by those who KNOW what they are doing even though they are over-whelmed by the enormity of the task.

> Even the snide remarks of some lame slime from Motorola has been
>laid waste.

"Lame slime?" :-) While some consider Public Relations folks in that category, that's just inflamatory, ignorant rhetoric from a nurse who has no provable record of past "experience" in either radio communications or the electronics industry...a wannabe-warrior who can only "fight" by cursing others who don't agree with him. Disreputable activity.

Such inflammatory curse words are only in the minds of a few who have NO REAL CONCEPT of the many and various communications systems used by the "infrastructure." Motorola has been one of the leaders in radio since World War 2...surviving when Hallicrafters and Zenith

and a number of other electronics industry biggies of the Chicago area FAILED, dissolved, went bankrupt, became DEFUNCT.

The electronics industry of the United States IS HELPING, just as it did after the NYC disaster of 11 Sep 01, shipping in professional radio-electronics equipment from handhelds to "WiFi" and "WiMax" whole systems to restore the BIG communications needs along the Gulf coast. The evidence IS there in the "MAJOR news", in the newspaper business section, in the press releases of major electronics industry corporations. It isn't carried on the amateur "news" from the ARRL...such is counter-productive to promoting the ARRL and furthering the amateur mystique that some need to justify their imaginary glory of having an amateur radio hobby.

The disaster of hurricane Katrina is of unparalleled proportions and ALL humane-thinking citizens can do their part, however big, however small. There is NO AID given to anyone or anything by continuing an unrelenting stream of personal insults towards others they know nothing of nor nothing about.

I shouldn't, but will. You don't say, but I think you are puzzled by a decreasing load impedance causing a decrease in collector current. I'd have to think about it, but I'd first Try modeling that LC filter at resonance to see if it gives an inverse function like the 1/4 wave line.
A "gut" reaction tells me that a decreasing collector current for *either* an increased or decreased load Z would not be a surprise...

did you you bother to read my remarks before lighting up the flame
thrower?

But just How big is Mntgomery I was though there once long ago, and
thought it pretty small. But any reason they could not use GRMS or even
CB to make those links? I don't see any but you might know better than
I.

as to your other points.

One am unable judge for myself directly of course because of rules you
personaly have supported for years.

Two I said most com seemed to that most were H&W, Indeed given the size
of Montgomery could not they diespense with anything but messagers? Not
syaing they should but couldn't they.

The Comms provided by hams are important and of value, But I see no
report of (let alone have one confirmed) use of ham radio that rises to
the level of critcal

>
> The Alabama Net and other groups are providing links further down the line.

and what are they passing?

what vital message are they conveying?

I am looking to set up a laptop on a boat that will receive wifi
signals. I need to install a twenty foot cable from the antenna to a
Proxim orinoco 8011b/g gold wireless card. I have found the cable but
don't know what antenna to attach to it as I want to minimize loss of
signal and I believe I have to get a certain length antenna to
synchronize with the cable length to do this. Does anyone know what the

right size antenna should be? Also, any suggestions on where to pick
one
up?
I found the cable here

Mostly? This is a left-handed complement in light of the news.

>> > It does not properly replace the system used by the cops as witness the
>> > keystone cops bummbling we see and here about

In fact it did replace the system used by the cops, and witnesses
abound.

>> > the ARS is not saving the day or saving civilation, it is hellp people
>> > lessen the impact of the disaster, what I have been saying all along

Well, until you were crossposted here, we have been entirely unaware
of what you have been saying all along. That aside, and more to the
point about your comment about ARS not saving the day, there are a
half dozen FEMA workers who would humbly admit otherwise after they
were rescued through Ham operator efforts.

>But just How big is Mntgomery I was though there once long ago, and
>thought it pretty small. But any reason they could not use GRMS or even
>CB to make those links? I don't see any but you might know better than

From your vantage deep in Virginia, I would think that Montgomery
would be quite cosmopolitan. Going beyond that however, such
suggestions as offered above seem to miss the point of HF
communications.

>The Comms provided by hams are important and of value, But I see no
>report of (let alone have one confirmed) use of ham radio that rises to

You should consider your choices made in informing yourself.

To Others,

I've rummaged up at least a couple of dozen references to the Ham
activities from a variety of news outlets (and not just the bobbing
heads of salacious cable TV). It would do us all well to stockpile
such commendations to "remind" authorities who so quickly forget in
the face of those who can stuff their pockets with money-for-airspace.

Hi Petercc

I have some interest in a similar project with WiFi. Forgive me if I'm
not understanding what you want to do.

Are you sure that card will fit in your lap top? All the lap top PCMCIA
WiFi cards I've seen, that have a coax connector, use a much smaller
connector.
You didnt indicate if you know from which direction the WiFi signal is
coming from. does the marine antenna need to be omniazimuth?
Are you willing to accept the signal loss associated with the 20 feet of
coax?

My weather conditions are not as extreme as your marine environment. I
have installed a wireless Ethernet bridge at the antenna and connected that
to the computer with CAT 5 to alleviate the line loss problem at 2.4 GHz.

E-mail me if you want any info and/or pictures of what I'm messing with.

Jerry

YEP!!

134 feet long.

Fed 46 feet from one end with a SINGLE WIRE [NO COAX, NO TWIN LEAD, NO BALUN, etc.]. Very good tuning system required. Allegedly something close to 600 ohms at feedpoint. More wishful thinking than reality. [In those days people were not obsessed with VSWR = 1.000001 to 1.]

Some feed lengths produced a 'hot' key or mike. Changed length of feedline to get rf out of shack. X

80, 40, 20, 10 meters.

All current model 'Windoms' are true fakes !!!

Virgina? I don't live in Virgina

but in responf to a quip about the shelters in Montgomery being linked
by Ham radio HF would hardly seem likely to be involved

337. lf to HF preselector design needed

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-10 02:01:27 UTC
From: TRABEM <>
Message-ID: <9df4i1546l564jt5uc22lp8gva22v9qdgi@4ax.com>
Source record: 70834
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I need an LF to 30 Khz preselector (passive) for a homebrewed receiver I'm building. I have most of the details worked out, but I am stuck on the preselector design.

I want one band to cover 50 Khz to 500 Khz (or 1 Mhz). The second band would be 1 Mhz to 30 Mhz. 50 ohm input with moderate Q (don't want to have to retune it every 100 Khz. The LF unit can be very high Q, peaking it every few Khz is ok as most of the signals in that range are narrowband signals anyway. Input impedance is standard 50 ohms.

I'd REALLY like to have one assembly do the entire job, but it appears to be a tall order as that's quite a wide range to cover with one tuned circuit.

Google returns to many hits even if I narrow down the search parameters, I tried google.

It appears I need to use some sort of permeability tuned variable inductor in conjunction with a variable cap. Have no idea how to go about this or where to buy permeability tuned inductors.

Any suggestions?

I'd suggest you post your question to some of the Internet wireless or networking newsgroups. I've seen questions similar to yours posted on some of them recently, such as, comp.os.linux.networking . I've also seen some good antenna sources given in posted responses there.

All Things Considered, August 30, 2005 ï¿½
While cell phones and other communication networks were demolished
by Hurricane Katrina, a group of radio operators volunteering with the
Red Cross have been instrumental in assistance and relief efforts.

NORTH LITTLE ROCK -
... Temple is president of the Central Arkansas Radio Emergency Net.
When Hurricane Katrina knocked over cell phone towers and utility
lines, ham radio became a key communications tool.
Temple says ham radio operators have acted as go-betweens for
Louisiana hospitals needing help and Arkansas aid workers.

Ham radio operators provide vital link after storm
Thursday September 01, 2005
ROANOKE, Va. (AP) ... Then an urgent voice sliced through the static,
clear as a bell.
``I have a diabetic, 80 years old, out of food and water for the
last 24 hours,'' it said.
An elderly woman from Bush, La., was stranded in her home after
Hurricane Katrina and desperate for food and insulin. Somebody sent
the message out over the air. Other voices picked up the call and it
was relayed all across America until, with luck, it would reach a
local rescue squad.

Local Woman Helping Hurricane Victims Via Ham Radio
Aug 30, 2005, 08:00 PM
A woman in central Indiana took control of one of the most powerful
emergency networks anywhere to help those effected by Hurricane
Katrina.

Somehow, somewhere in the middle of all the hurricane mess, someone is broadcasting to the world probably operating on battery power and a makeshift antenna.
Tuesday night, Indiana handled the call.
For an hour, Peggy McNary took the post of "controller" of SATERN, Salvation Army Team Emergency Radio Network.... "A family called out on a cell phone, trapped in an attic. They got word to an amateur radio operator somehow just before they lost contact, SATERN was able to contact the Coast Guard and that family was rescued," she explained.
The network claims a hand in dozens of Katrina rescues already and will operate until there is no need for more.

Local ham-radio operators help rescue effort
By Rocky Scott
DEMOCRAT STAFF WRITER
Tallahassee ham-radio operators took part in the daring helicopter rescue Friday of about 1,500 patients and staff from two New Orleans hospitals besieged by darkness, dank water and gunfire.
...
Looting and gunfire erupted and 100,000 stranded, scared residents became a force ready to spill into anarchy.
Enter the Tallahassee Amateur Radio Club, Florida Division of Emergency Management and some old-fashioned ingenuity.
State Emergency Management officials suggested Hall contact the local ham radio club to solve the communications dilemma.
Urged by rapidly rising water - 8 feet deep in places - and the growing knowledge that New Orleans had become a drowning pool, the ham operators fashioned a satellite reception device atop an 8-story building in downtown Tallahassee.
Then three of them - Theo Titus, Gene Floyd and Bill Schmidt - all boarded a helicopter in Tallahassee Wednesday and headed for New Orleans.
Atop the garage at Tulane, they set up a generator-powered ham radio with a satellite uplink.
By Tuesday afternoon, the choppers were up and running, and Hall and his co-workers in Tallahassee were able to give directions to pilots....

That would be 1:10 (or 1:20) frequency range.

>The second band would be 1 Mhz to 30 Mhz.

That would be 1:30 frequency range and would require a 1:900 reactance range, if only one element (inductance or capacitance) is tuned, which would be completely unrealistic. The alternative would be to tune both the inductance _and_ capacitance in the 1:30 range. However, with a 300 pF variable capacitor, the minimum capacitor would be 10 pF _including_ all stray capacitances, not very realistic. I have no idea what a realistic tuning range would be for a permeability tuned inductor. I have only seen those in FM receivers (87..108 MHz), which only about 20 % tuning range.

>50 ohm input with moderate Q (don't want to
>have to retune it every 100 Khz. The LF unit can be very high Q,
>peaking it every few Khz is ok as most of the signals in that range
>are narrowband signals anyway. Input impedance is standard 50 ohms.

Maintaining the constant impedance if both inductance and capacitance is tuned would be a challenge.

While maintaining the power match makes some sense in HF receivers (and also if you are using some small magnetic loops on LF/MF), but otherwise, I would question the idea to maintain the 50 ohm resistive input impedance on LF (and possibly also MF).

On LF, any practical random wire antenna would have a high capacitive reactance. On LF I have simply used a parallel tuned circuit and connected the antenna to the hot end of the circuit with a small (10-100 pF) capacitor. Of course, the tuning scale will not be accurate if you change the antenna, since the antenna stray capacitances will detune the resonant circuit. Use a secondary winding or a source/emitter follower to get the impedance down to feed a 50 ohm receiver input or feed a coaxial cable (if the preselector is just under the antenna).

If you intend to use magnetic loop antennas on LF/MF, which have a low efficiency, I would suggest using a (remotely)tunable loop as the preselector, with possibly a preamplifier at the antenna.

I would strongly suggest splitting the HF bands and switching in various inductors for various bands and use an ordinary variable capacitor.

The situation is quite problematic on LF, since you would need a variable capacitor with a tuning range int several nF to keep the resonant circuit impedances at manageable levels (otherwise, it would be quite "touchy" due to stray capacitances). With practical variable capacitors, you would have to add parallel padding capacitors, with would further reduce the tuning range.

Permeability tuning might be an option. You could try making a coil and slide a ferrite bar (from a medium wave antenna) into it, however, I have no experience with this.

greetings...

I have been a ham since the mid 60's and the main antenna of choice appears to be dipole... However, over the past few months, or so, I have been reading more and more about this loop antenna.....

I am reasonable sure I can get more information about it so I won't bore you with how to build one, etc, .. my question is more of why or how... Why has this antenna become so popular over the past little while and how did it get this popularity....What charateristics, besides seemingly not needing as much geography to need to put up, does this antenna have that make is so appealing?

I might consider it...for 80 or 40...

Depending upon the size of the loop in wavelengths and depending upon
where in the geometry it is fed and depending upon its height, it
might very well be a good cloud warmer - in which case it would
probably give excellent performance in the immediate area (as opposed
to DX).

People that I QSO with on 75 seem to do very, very well with loop
antennas in the evening over a range of up to 500 - 700 mi.

I realise that you are after a passive solution but I wonder if an op-amp or two in a Q multiplier configuration *for the first band) might be a better idea? You could then tune the feedback/gain of the device with a R/C combination rather than large values of L. You could of course set the gain to 1 if you wanted.

Just an idle thought.

> an increased or decreased load Z would not be a surprise...

The output is link coupled through a series 216 nH coil and a 2.1 nF cap
to ground. The load is connected from the coil/cap junction to ground.
It's a Class E/F 40m amp.

Load Drain Current Drain Efficiency Load Power
25 ohms 12.2 amps 82.6% 129 watts
50 ohms 20.1 amps 77.7% 200 watts
100 ohms 33.1 amps 62.3% 264 watts

Can these be thought of as load-pulling data points? Maximum load
power appears to occur when the load is greater than 100 ohms.

Hi Larry

You are talking about a shielded magloop rather than a full wave length
single quad loop...

They exhibit reasonable performance for their size and are very quiet.
ie the signal to noise is often better on the magloop than a larger
antenna. I have seen claims that the signal strength is maybe 2 S points
lower but the noise is 5 S points lower.

I have heard of configurations where a dipole is used for TX and a
magloop for RX.

The at antenna tuning makes for less chance of a strong nearby signal
desensitizing your RX. The downside of that is that you have to have
some method of doing this remote tuning. Bandwidths in the order of
20-30khz on 80m are not uncommon.

They can be built for 2:1 or 3:1 frequency coverage range. I have no
idea how the performance changes at the far end.

I actually havent built one <weak grin>

Hope this helps.

Cheers Bob W5/VK2YQA

ANYONE knows better than you.

(1) There are only 35 ACTIVE GMRS licenses in Montgomery per the
FCC. To the best of my knowledge, there is NO active GMRS repeater in
Montgomery. However, with only 35 licensees, I find it hard to believe
there's more than one if there's any at all.

This means a MAXIMUM of seven repeater pairs and 14 simplex
channels and no more than 25w to fixed antennas, period.

(2) There are 378 AMATEUR licenses in Montgomery. My 2004
repeater directory shows (6) 2 meter repeaters and (6) 440 repeaters in
the city alone.

On the 2 meter band alone this includes five digital-exclusive
channels, over 30 simplex channels, and authorized power of up to
1500w.

(3) CB Radio has a ground-wave effective distance of less than 5
miles. Daytime propagation makes it completely unusable more than 2
miles away.

(4) There is no viable CB radio-based traffic handing system in
the United States. You can tattoo the message to the CBer's head, but
if they don't have the infrastructure to disposition the message, all

you've done is waste time.

(5) Montgomery's population is just under 250,000.

I have a new 2005 Buick with a rear window heater/antenna. The heater works and the FM reception is fine but the AM reception is terrible to almost nil.. The dealer is working on the problem with the AM radio reception and has ordered a new cable which they are going to install when it arrives later this month. I doubt that this is the problem but they think it is so we'll see after they install a new one. I'll post a follow up when they figure out the problem with the AM radio. My guess is that it is the radio but that is just my guess.

Thanks Paul,

My old Drake C line had a multiple ganged permeability tuned inductor mechanically coupled to a variable cap.

One of the assemblies tuned the front end, one peaked the driver stage, etc.

It covered from 1 Mhz to 30 Mhz with a half turn on the front panel preselector control. Most likely the variable C and L tuned together maintained a desirable Q across all the bands.

I was hoping for something similar, but have no idea where to get permeability tuned inductors today.

Regards,

T

That is incorrect. All the traffic I personally relayed was
emergency requests for rescue. All the traffic handled by
the net I helped was emergency traffic, and resulted in many
many rescues. Lots of folks are alive today because of ham radio.

HI Cecil and the others...
How long ....
This is one of the things I would have to research if I was interested on one...
In my imagination.. I have been thinking of these loop antennas as being sort of a very large coil of wire as the input tuned circuit of the first rf amplifier...
As the coil gets larger, in diameter, you need fewer turns.... So, by extension, if you had a large diameter tuned circuit, let say 10 feet, you would need very few turns... Unfortunately, .as well any tuned circuit, you need a parallel capacitor... As you changed frequency, since we normally change the capacitor, you have to remotely change the parallel capacitor...
Ok.... So you have this rather large loop, inductor, and you have it's parallel, capacitor you have to peak them (I believe I have already said that).. Now. since our cable usually comes in 50 ohm impedances.... you have to transport this weak signal to the radio, you have to use a split capacitor.... the full capacitor is in parallel with the coil.... The ground capacitor, of the two series capacitors, is adjusted to give the proper match to the cable and the series capacitor is the parallel to the coil, you have a very marvellous network of two capacitors, needing separate tuning to keep this overall loop tuned...

A lot of work.... I just hope this loop antenna system can be used in both transmit and receiver... (just my initial opinion)....

Any further thinking on this subject... you have my attention...

Yes I would like an email address so I can see what you are talking about.

I have the cable connector which connects to the main cable from the proxim card fine. I am picking up the 20 foot cable and want an antenna that will minimize loss of the signal. I tried an existing omni antenna that is aboout 30" long and a long cable and the signal was nonexistant. With the short cable and that same antenna I was using, I got some hotspots tuned in.

Hi Peter,

This 30" antenna is easily ten times too long. It will be very
directional, and only if you point it (like a rapier) towards the
transmitter. As it stands, your favored direction is straight up.
This, of course, is strictly counter to your stated desire for "omni."

Take a cue from the products offered for this class of communication.
Their antennas are short for reasons that go beyond aesthetics. Take
heart that you are on the right path. Antenna height (distance above
you, not length) is always an advantage.

I just bought a very old, vertical antenna. The ant. is aluminium
andvery corroded.
Is this just a cosmetic problem, or will the corrosion affect the
radiation/reception of RF?
Since the insulation on wire antennas doesn't affect their
effectiveness, I'm thinking the corrosion wouldn't be a problem; but my
working-class logic has gotten me in trouble before. <G> Will painting
an aluminium antenna decrease it's effectiveness, or not
matter? Thanks

> Bob -

> If you wish to clean the aluminium - lye (NaOH) is often used -

> Although some amateur use steel wool pads -- this can leave steel
> slivers on
> the aluminium tubing that can oxidize (rust) - I refer non metallic
> scrubbing
> pads if you need some elbow grease.

Hmm. Grey matter being a bit thin now, and about 40 years since I was at
school, but doesn't caustics on aluminium cause dangerous gases? Better
to use a scotch bright pad and an agent like Brasso (English name for
Brass cleaner compound) Once you've tin worm it's hard to stop the
oxydization. Your main priority is making sure the antenna has no
weaknesses in the wall thickness so that it's safe and will not bend.
Painting should have no detrimental electrical effects providing the
paint has no metalic compounds in it, but surly painting is just hiding
defects!! A previous posting asked about using stainless steel fixings
on aluminium, this causes an electrolitic conversion between the two
metals, not quite a good combination especially if you've shelled out
mega bucks for a decent antenna. After a few years in the air without
inspection you's be in for a big surprise.
Cheers from England. Dave

Hi Peter

I sent you an E-mail. Let me know here if it doesnt get to you.

Do you have any specs on the "existing antenna"? I havent seen any
omniazimuth WiFi antennas that long. It is likely that the 30 inch long
antenna is *not* designed for 2.4 GHz use.

Try to get some specs on the loss of the cable you are "picking up".
Since I am not willing to accept the loss associated with coax at this
frequency, I have resorted to either USB or CAT 5 rather than use coax from
the antenna to the computer.

Jerry

Full wave loops are quite different from small loops but both
can be used for both transmit and receive. As usual, transmit
is the challenge. A one-turn small loop works best if resonated
by a vacuum cap.

> Any further thinking on this subject... you have my attention...

The ARRL Antenna Book has some good information on the subject.
Single turn loops work well for transmitting. Multiple turn
transmitting loops have a nasty habit of disappointing the user.

>>The Alabama Net and other groups are providing links further down the line.

> and what are they passing?
>
> what vital message are they conveying?

Several days ago I heard a message being relayed to police/hwy
patrol/whomever about people trapped in an attic somewhere that needed
to be rescued.

The latest ARRL eLetter reports that in some places hams were lending
their equipment to "official" agencies because the latters' equipment
did not work.

Remember that, in this "land of the 'We'll do it our own way, thank you
very much'", many govt. agencies cannot communicate with each other by
radio even when the equipment does work: every county and municipality,
every fire dept. and ambulance service is free to decide what equipment
to use regardless of what anybody else is using. I understand that
Michigan is one of the few states with an integrated (or at least
coordinated) radio system. Where multiple agencies are trying to work
together, putting ham radio operators with each agency may be one of the
few ways they have of keeping in touch.

What's "off topic" about it, Markie..?!?!

YOU were the one who brought up GMRS and CB, Ya Putz!

And you will please notice that I clearly addressed SIMPLEX
frequencies too, so so much for your "repeaters only" diatribe, Markie.

> all you do is rant mostly about things with no relavnce even make
> claims that the laws of physics change somehow for cb hf

(1) YOU brought up GMRS and CB radio, Markie, NOT ME!

(2) I didn't claim any "laws of physics" were different for "cb hf" ! I SPECIFICALLY addressed the shortcomings of using CB radio BASED upon KNOWN propagation at that wavelength! It's the SAME reason that 10 meters is not typically used for short range emergency communications here! Add the horrific QRM on 11 meters, and it's a wasteland good for nothing except in-house intercom duties, IF that!

> no reason advanced why the shelter even the radios at all all could be
> handled less effectively perhaps by the people driving supplies to the
> shelters
>
> I see a lot of posturing

No...what you SAW here were some FACTS.

QUOTE

(1) There are only 35 ACTIVE GMRS licenses in Montgomery per the FCC. To the best of my knowledge, there is NO active GMRS repeater in Montgomery. However, with only 35 licensees, I find it hard to believe

there's more than one if there's any at all.

This means a MAXIMUM of seven repeater pairs and 14 simplex channels and no more than 25w to fixed antennas, period.

UNQUOTE

What is "posturing" about that, Markie? Nothing there is mistruthful or deceitful. Also please note the aforementioned use of OTHER-THAN "repeater" options that you tried to claim was my only point.

QUOTE

(2) There are 378 AMATEUR licenses in Montgomery. My 2004 repeater directory shows (6) 2 meter repeaters and (6) 440 repeaters in

the city alone.

On the 2 meter band alone this includes five digital-exclusive channels, over 30 simplex channels, and authorized power of up to 1500w.

UNQUOTE

One correction on my part...There are "374", not "378" Amateur licensees in Montgomery...And that's just folks with a Montgomery mailing address.

Again...I'd be interested in what part of those numbers are "posturing", Markie.

And again, OTHER than "repeater" options are addressed.

QUOTE:

(3) CB Radio has a ground-wave effective distance of less than 5
miles. Daytime propagation makes it completely unusable more than 2
miles away.

UNQUOTE

You dispute this, Markie?

QUOTE

(4) There is no viable CB radio-based traffic handing system in
the United States. You can tattoo the message to the CBer's head, but
if they don't have the infrastructure to disposition the message, all
you've done is waste time.

UNQUOTE

Wondering what part of THAT is "posturing", Markie.

P L E A S E point me to the URL for the CB-radio based traffic
handing organization in the United States...Please...

QUOTE:

(5) Montgomery's population is just under 250,000.

UNQUOTE

YOU said that you remembered Montgomery as being small. So now
the Census numbers are "posturing"...?!?!

> It was nice for that other poster a list a few life saving events,
> though are worth knowing about.

Stuff like that is going on every day right now. It will be a long
time before Motorola and the other manufacturers can get the gear into
the field and working.

So...Amateurs created KATRINA just so we could "posture" in a
newsgroup...?!?!

Steve, K4YZ

365. Re: loop antenna question...

Source record: 70861

It should be borne in mind the best form of radiator is just an isolated straight length of wire. But curved or bent wires do almost as good.

Loop antennas are nearly always single turn conductors and provide a means of getting as much wire into space as possible with the largest possible linear dimension being dependent on the size of your back yard. Or your attic. Loops are space savers.

Subject to the space available, for a given perimeter, the larger the area enclosed by a loop the better are its radiating properties and its power efficiency. However, when an antenna is already 80 or 90 percent efficient, there is seldom any point in attempting to improve it. 100 percent is impossible. And to improve it to 95 percent results only in an entirely imperceptible 0.2dB or 1/20th of an S-unit.

Again considering space requirements, the physically smallest loops are descibed as Magloops. Magloops, not difficult to design, are the most efficient of all small antennas of any type.

When the perimeter of a Magloop is only 1/3rd of a wavelength at the operating frequency, efficiency can approach that of a full size 1/2-wave dipole. The disadvantage of a small magloop lies in its restricted range of operating frequencies. Three adjacent HF bands at most. The cost of a vaccuum variable capacitor cannot be neglected.

But even at frequencies as low as 1.9 and 3.6 MHz, magloops with perimeters as small as 1/15 wavelengths, diameters as small as 1/50 wavelengths, are quite usable in small backyards and attics. Expect signal strengths 2 or 2.5 S-units worse than a full size half-wave dipole. There are reports of improved signal to noise ratio on receive although I have not experienced this myself.

For design of magloops at any HF frequency and any reasonable size of loop, download program MAGLOOP4 from website below.

For performance of much larger horizontal loops, for use in your backyard, download program RJELOOP4

Reg, G4FGQ.

michigan is still working on this system sad to say although they are
trying fairly hard and have made a lot of progress compared to much of
the nation

Now the goof calls me a liar. I have been sitting on HF for the last WEEK helping the shelters talk with each other. Montgomery needs commo into places like the Gulf Coast, Biloxi, Gulfport, and of course New Orleans. Get a flippin map and tell me how VHF/UHF is going to make those distances?

Montgomery is the capital city of Alabama. Not what I would call a small town.

Sure they could. And if we still had WWI carrier pidgeons they could be
used also. Or perhaps they could mail a letter.

Then I suggest you listen in and find out what is being passed. I will be
posting on rec.radio.amateur. policy the statements from the ARRL on this
subject. Perhaps that will help you to understand.

>
>>
>> The Alabama Net and other groups are providing links further down the

>
> and what are they passing?
>

Everything from relaying between shelters (because of poor conditions, or
poor antennas or both), helping various operators with finding links to
other nets, Health and Welfare such as passing messages (at our expense)
from the disaster area to families of those in the area. I personally
participated in passing Emergency traffic from Huntsville AL to New Orleans

Coast Guard about a family trapped in a house and needing their help. Additionally I relayed between a very weak HF station in New Orleans to Tallahassee Hospital to "tell the aircraft to come up on VHF". I have no idea what that meant. But I have no doubt it was important to someone.

I am just ONE operator doing what I can. How about stop criticizing those that are.....you may learn something.

Just where did you get the notion that Montgomery only needed to talk across
town?

A follow-on from the previous message -

As usual, I forgot to mention the website from which the programs could be downloaded. It may be something to do with a bottle of fine vintage Port I have recently opened.

Download MAGLOOP4 and RJELOOP4 from website below and make what sense you can out of them.

Incidentally, the number 4 in each name is an indication of previous programs of similar names through which programs have been improved or diverted.

I never said any such thing. I was talking about comms in/out of shelters.
You think ALL the shelters are in one town?

Are you seriously this out of step with the rest of ham radio? Seek mental
health help. You have been fixed, right? Please say yes.

Perhaps I am indeed I suspect I like a lot of the long term memeber of
the tech class are largely cut off from the rest of Ham radio. OTOH
that is a result of decisions and rules you have supported for years

Sure they could mail a letter. After the US postal service reopens
mail service to the affected areas. There were notices on the USPS
website telling that next day, and some other mail services were not
available for the time being.

Fair Radio used to have some in their catalog, and they were used in
all of the old Delco (and some other brands) car radios of the '60s and
'70s.

Which means it was a colinear. It is long for a reason.

Similar antennas are vailable at CompoUSA and most other computer stores.

What you should look for is small plasic-encased bumps (each enclosing a coil) or obvious coiled sections spaced every few inches along the antenna's length. If it has those, it's probably a collinear like Tom says, and will be omnidirectional broadside to the antenna. If it doesn't, and is just a straight piece of wire or rod, it's directional nearly in the direction of the wire like Richard said.

Any reasonable sized coax will have a lot of loss per unit length at that frequency, so do everything you can to keep it as short as possible. Depending on the situation, putting the antenna might or might not help, if putting it higher necessitates making the feedline longer.

Just about all the radios I've seen with mechanical pushbuttons for station presets used permeability tuned inductors -- the pushbuttons each just positioned a ferrite core to a preset depth in a coil. It wouldn't be difficult to construct one, unless you're mechanically declined like I am.

Hi Tom

Isnt 30 inches a little too long for a colinear at 2.4 GHz? I'd guess
that the antenna that Peter has hooked up is a marine radio whip. I'll be
interested in reading more about what he is doing, and where the 30 inch
long antenna came from.

Jerry

You won't see that on these colinears, the radome surrounding them
covers it up. I am thinking they may be the coax style colinears, which
would not have the coils.

Well, he did specifically state WiFi, so I went with that.

And a colinear can be as long as you'd like, they just don't keep
gaining gain very well after a certain point.

Ah, good points. I hadn't considered either a coaxial (Franklin)
collinear or a radome. In that case, I can't think of an easy way to
tell except by pointing the antenna in the direction of a known signal
and seeing if it gets better (not a collinear) or worse (collinear).
Unless, of course, the manufacturer and model number are known or visible.

Tom

I must be out of touch with the current technology. I thought a 6
wavelength long colinear was too long for practical reasons. It seems that
beam squint with frequency change would rule out a 6 wavelength long
colinear.

Hi Tom,

And 30 inches (more than 6 wavelengths long?) would seem to have long
met diminishing returns. Given the prospects of it bobbing on the
ocean, with a successively dipping and rising critical elevation gain
- well that sounds like no kind of solution to a problem.

I once told one of the Vice president of marketing at United Video
Cablevision that he was mechanically declined and my boss freaked out.
;-) The VP yelled at him and told him to shut up because it was true,
and he was happy that whenever he had to launch a new channel in the
Cincinnati system that everything was set up and ready for him when he
arrived.

Of course, you could make them as individually tuned coils with a
stepper motor or servo per coil.

All,

I am trying to model a loaded vertical using EZNEC. It is fairly easy to start with the vertical model and extend or shorten it. I also think I created a load correctly. However I seem unable to connect the load to the vertical segment. How can that connection be verified?

Also, what type of also load supports a second connection to a second wire to simulate a mid load?

Thanks,
Dan

Hi Dan,

?? In the "Loads (R+JX)" window, you enter a desired position on a particular wire number, and the value of the load, which presumably would be a coil or a capacitor. It will tell you where the load actually got put on the wire, as it must be in the middle of a segment. You can adjust the number of segments to put the load closer to where you want, if it didn't come out close enough the first time.

A good way to verify that the load is doing something is to change the value of the load and look at what happens to the feedpoint impedance, which you can see in the "Src Dat" (Source Data) window. For example, if you start with a 10.3 meter vertical, 40mm diameter, 11 segments, over perfect ground, with the feedpoint (source) at the middle of the lowest segment, you should find that a coil of 0+j582 ohms gives you very close to resonance: close to zero imaginary component in the feedpoint impedance. Raising the coil reactance causes the feedpoint to become inductive: positive imaginary component. And lowering it causes the feedpoint to become capacitive.

Cheers,
Tom

To add to Tom's excellent explanation, let me add that you only need one wire to model the vertical. I suggest beginning with the Vert1.ez example antenna to get an idea of how it works. Look at the model with the View Antenna display. Then specify a load in wire 1, 50% of the way from end 1. The load will appear in the View Antenna display as a little square. The Loads Window (where you specified the load) will show that the actual position is 55% of the way from end 1, which is the closest EZNEC could place it with the specified number of wire segments. If you change the number of segments to an odd number, EZNEC will be able to place the load exactly at the middle. You can specify other positions in the same fashion, but it might require more segments to get it really close to where you want.

Source and load positions are specified in exactly the same way.

Copper will turn a pretty green colour and isn't particularly strong.
A steel coat hanger is traditional and works perfectly well.
Electrically, anything conductive will do. Your only considerations
are mechanical and appearance.

About 30 inches is an optimum length. Half that will do.

==========

The reason a multi-turn maggloop of the same diameter would be
disappointing is because of increased loss in the loop conductor.

The ability to collect or radiate signals is a function only of the
diameter, ie., the longest linear dimension. Alternatively stated, a
function of the area enclosed.

With a single turn loop, conductor loss is due simply to skin effect.

With a multi-turn loop and the same amount of copper, proximity effect
comes into play and loss resistance increases faster than radiation
resistance.

Also, with a transmitting magloop, for the same power input, the
voltage across the tuning capacitor increases proportional to the
number of turns. Ridiculously high voltages appear. Although, the
value of the capacitor in pF is very much smaller, the physical size
of the capacitor remains the same.

Reg.

Let me make sure I understand. First I used the LCR configuration, that should not make a difference? Are you saying a load is placed in the middle of a segment? If I wanted to create a center loaded vertical one way would be to create a 1 wire antenna and place the load in the middle? Is that correct?

Thanks,
Dan

Thanks to all that commented. Although I don't have an answer, the content of the discussion was helpful.

I'm not exactly fond of electronic switching, but it's probably adequate since atmospheric noise dominates in the vlf and lf range anyway.

I'm trying to understand the butterworth filter now, with the hope of designing a bandpass filter over a wide range of frequencies rather than a variable unit.

You seem to be exceedingly knowledgeable about loop antennas. I have limited space available for a 160 meters antenna. What advice do you have about a loop antenna for 160 meters constructed out of 3/4" copper pipe with an octagon shape, and a perimeter of 100 feet. The plane of the loop would be vertical with the bottom of the loop about one foot high. The loop would be fed at the bottom, and the remotely tuned series capacitor would be centered in the top side of the loop. Does this project seem doable and does it make sense?

Roy and Tom,

Thank you. I actually tried that as one experiment. The loads window showed the connection as you described. When the antenna is configured close to what I expect there is a resonance near the intended frequency. So that is progress. Now I am just trying to tweak the parameters.

On the SWR scan is there a way to print or plot the step outputs? I am trying to determine the resonance point.

Thanks,
Dan

I'm assuming that "drive a class E amp with an SSB signal"
means an SSB signal on the input, i.e. linear amplification
is required. How does Mr. Sokal linearize the non-linear
characteristics of the Class-E amp? I'm not saying it can't
be done - but I don't know how to do it and there's no claim
of linear operation on any of the Class-E Amp web pages.

its only required if you want the output to sound like the input. there are
lots of amplifiers on 27mhz and other bands where this is not a requirement.

There's one point of caution. The lumped load function will
not accurately predict the phase shift through a real-world
coil. Many antenna designs use phasing coils. The lumped load
feature of EZNEC will not accurately model those antennas.
If phasing coils are used, the EZNEC helix option should
be used which does seem to model the phase shift through the
coil.

Well, maybe I presumed too much. I certainly wouldn't like it but
of course, I wouldn't force my likes and dislikes on everyone. :-)

All,

Thank you for your help to get the basic model in place. It seems to be working except that ground resistance does not appear to be modeled. This may be an oversimplification my part in how the source is defined or connected. It is a simple source connected to the first, lower, segment. The end of that segment is also connected to a radial system of 8 quite short radials. I would expect to see the feedpoint impedance reflect the ground system. However, it seems to reflect the vertical element only. That value is very close to a theoretical loaded element over a perfect ground. This ground is a medium ground so it should have some visible effect.

Is it obvious what am I doing wrong?

Thanks,
Dan

This is to 'an old friend' in particular and his dingaling buddies.

Perhaps this E-Mail I just received from the Alabama Section Emergency Coordinator will "HELP" 'an old friend' to understand. Anyone want to bet?

Please notice the comments about using tactical and formal message handling. FYI tactical would be to dispense with the formal headings. Just use the basic address/phone number. Then the operator that received the message makes a phone call to deliver anywhere in the world that allowed 3rd Party traffic.

Formal should be self explainatory, but knowing the abilities of Mr. 'an old friend' I'll translate....It is using standard ARRL Formatted messages as in;

Number 139 W (Welfare) W4NTI CHECK 12 ANNISTON AL SEPT 10
TO MR JAMES KIRK
STARSHIP ENTERPRISE
ANYWHERE IN THE UNIVERSE ZIP CODE
PHONE NR
BT
ALL IS WELL HERE MR. SPOCK X HOPE
TO SEE YOU SOON BT JAMES T. KIRK

BT

NNNN (MEANS NOTHING FURTHER) (USUALLY SENT IN CW OR DIGITAL MODES AND NOT USED IN PHONE)

You do notice the word 'sites' right? That is plural for many locations.

I especially want your response to the paragraph concerning the highly vaunted 800 mhz system. That FAILED immediatly. Then please comment about the use of Hams to DISPATCH Police and Fire. Not to mention the comment of how these same hams helped FIX these sites to attempt getting the Police and other Emergency agencies back on line.

Please also note that these Ham teams VOLUNTARILY PUT THEMSELVES into the middle of one of worst, if not THEY worst ecological disaster in this countries history. Providing their own equipment, their own supplies, their own gas, etc. Note how much that is appreciated and does not ADD to the problem.

No bragging, no looking for headlines, in fact NO NAMES AT ALL. So tell me 'an old friend' where is all the bragging????????

I doubt this will do a bit of good with you and your 1/3 of the newsgroup
that support you. But these are the facts. Believe it if you want.

OR.....just remove the egg off you face and drop the subject.

Dan/W4NTI

The ARES E-Letter
Special Edition
September 11, 2005
==========

Edited by Rick Palm, K1CE

==========
ARES reports, other related contributions, editorial questions or comments: Rick Palm, K1CE, k1ce@arrl.net
==========

SPECIAL EDITION TWO: HURRICANE KATRINA FOLLOW-UP

It's been quite a week of studying the ARES response to Hurricane Katrina while keeping a wary eye on storm Ophelia, just off shore here in Flagler County, on the Florida central east coast. Local ARES was on alert. We had winds and driving rain as Ophelia tried to decide which way to turn. Yesterday, it marched to the northeast and today we have an uneasy, almost surreal calm. But, the sky is clear.

Back to Katrina: I can't remember a more comprehensive ARES response, especially in terms of inter-county and interstate mutual assistance, plus the concomitant, unprecedented activity by ARRL HQ staff in support of that response, ever. Even the Chief Operating Officer Harold Kramer, WJ1B, worked over the Labor Day holiday weekend. And word arrived yesterday that the "Hurricane Katrina Amateur Radio Volunteers Needed Clearing House" now is live on the ARRL Web site <http://www.arrl.org/FandES/field/agencies/>. The ARRL Letter: "This database will be the primary means for relief organizations requiring Amateur Radio volunteers for communication support to list their needs. Additionally, volunteers looking to help may search the listings to match up their capabilities with the various requirements." That is a first, as far as I know. Credit Joe Tomasone, AB2M, for the Hurricane Katrina Disaster Communications Volunteer Registration and Message Traffic Database he developed.

On the Northern Florida ARES Net this morning, a report was made that "renegade" hams were turned away from an affected area and were to be

adorned with "metal bracelets" if they did not leave. Message: Coordinate your volunteer efforts with your own home ARRL Section Emergency Coordinator (SEC), or his/her designees. Also, be prepared to be self-sufficient: "If you need it, you bring it," advised Alabama SEC Jay Isbell, KA4KUN. - K1CE

"All of us know this will be a months-long effort. Just because we are unable to immediately send those of you who have registered, that does not mean we will not need you in the future. Your patience in awaiting an assignment that may never come is appreciated. The requirements are likely to change in the future; we are unable to give any idea of when that will be." - Jerry Reimer, KK5CA, STX SEC

==========

+ NORTHERN TEXAS SECTION RESPONSE

The NTX Section had been on alert since Monday, August 29. NTX SEC Harris Swan, K5MWC, and STX SEC Jerry Reimer, KK5CA, had agreed early on a plan to make effective use of NTX ARES members in response to requests from the affected area. That plan was to prepare a list of people volunteering to go if requested; Reimer would coordinate all requests for assistance.

NTX ARES has primarily been supporting the West Gulf ARES Emergency Net, dealing with H/W traffic, and supporting Red Cross, Salvation Army, and FEMA. Several of the county EOCs requested support as they anticipated operations with the large number of evacuees expected.

NTX will supplement resources in the affected area, provide support to local shelter operations and support relief agencies in response to their requests. The tempo will certainly pick up as time goes by; NTX ARES is planning for long-term needs. -- NTX SEC Harris Swan,

K5MWC

The following is culled from a status report by the indefatigable Jerry Reimer, KK5CA, South Texas SEC: Hurricane Katrina ARES operations continue in Louisiana, Alabama, Mississippi, North and South Texas sections, using operators recruited from Louisiana, Arkansas, Mississippi, Texas, Tennessee, Florida and other nearby states and sections.

+ LOUISIANA

ARES continues to support Red Cross shelter and Southern Baptist Convention debris-clearing operations in St. Tammany parish, where disaster relief workers are housed and fed at the First Baptist Church in Covington. In Washington Parish, ARES operators are arriving to provide critical communication among hospitals and the parish EOC. Over a dozen operators from Texas alone have traveled to Louisiana. Victoria County (Texas) ARES EC John Wagner, WA5VBP, flew into the New Orleans airport where it was determined that his assignment was unsafe; he was sent on to serve in Baton Rouge.

Communications among the field teams and the state EOC in Baton Rouge continues using HF voice on 75 meters and 40 meters. Surprisingly, many VHF and UHF repeaters remained operational after the storm's passing. Louisiana SEC Gary Stratton, K5GLS, temporarily delegated his authority to former SM Al Oubre, K5DPG. Stratton will be working on restoring the communications infrastructure.

In yesterday's ARRL Letter, Stratton was cited as saying Amateur Radio was the only means for state officials at the state EOC in Baton Rouge to communicate earlier this week with parishes above Lake Pontchartrain. Also, there was a communication to the EOC from FEMA that said, "Ham radio is our prime communications with you, and they should get anything they need."

Reports also have ARES ops even loaning government agencies their equipment.

+ MISSISSIPPI

The hardest hit areas are perhaps the counties closest to the Gulf coast, especially Hancock and Harrison Counties. ARES DEC Tom Hammack, W4WLF, requested 25 ARES operators for critical communication among EOCs, hospitals, and shelters. ARRL Northern Florida, West Central Florida and Southern Florida Sections are sending self-sufficient teams to meet this urgent need, and a few operators are coming from Arkansas. Hammack said his operators are sleeping on the floor where they are assigned. State RACES Officer and ARES DEC Ron Brown, AB5WF, is working on a staging area for Amateur Radio responders near the Mississippi Emergency Management Agency (MEMA) in Jackson. Mississippi SM/SEC Malcolm Keown, W5XX, received a replacement generator and now has telephone and Internet

service.

[In correspondence with Malcolm, he gave me an appreciation for their mental status and what they are going through on the ground in Mississippi: "At this point nobody has much time to document activities. Nobody at this point really has a clear enough mind to put together a coherent story." -- K1CE]

+ ALABAMA

The state capitol of Montgomery was the scene of processing and orienting Amateur Radio volunteers for Red Cross and other duty in Louisiana and Mississippi. Some volunteers will help support communication at Red Cross shelters set up for evacuees, while others will provide tactical communication for feeding stations or for emergency management. Alabama SM Greg Sarratt, W4OZK, has been coordinating ham radio volunteers at the Montgomery site. - ARRL Letter

+ SOUTH TEXAS

The Red Cross reports housing more than 142,000 people in 485 shelters in 18 states. Texas has over 230,000 people who fled. Orange County ARES EC Rocky Wilson, N5MTX, has ARES operators supporting seven Red Cross facilities that include distribution centers and shelters. Since being activated on August 27, 35 ARES operators have provided over 1,200 person-hours, as operations continue. ARES groups from adjacent Jefferson and Polk Counties are providing much-needed mutual aid.

ARES District 14 (Harris County) DEC Ken Mitchell, KD2KW, was requested by the county emergency management office (HCOEM) to provide four operators 24 hours per day, on-site at the Houston Astrodome, and two at the county EOC, beginning September 1. Since then, more than 90 operators have provided over 720 person-hours of direct communications support. All four county ARES ECs are providing operators at both sites.

Managing the incoming health and welfare inquiry messages is overwhelming nearly all NTS resources, especially at the local level. To mitigate this, Amateur Radio clubs have been asked to contact nearby shelters as often as possible to pick up outgoing messages and process them into the NTS by any available means.

At the request of the state Adjutant General's office, Travis County ARES EC Don Dudley, AC5YK, facilitated National Guard in Waco with communication with Guard elements at the Louisiana Superdome.

+ NEW ORLEANS

STX SEC Jerry Reimer, KK5CA, reports: "Amateur Radio operators are beginning to be sent into areas around New Orleans to support command and control operations for Red Cross and other disaster relief

operations. The equipment requirement is VHF and UHF FM. Portable, hand-held and mobile stations are needed. Conditions remain primitive. A pass is required from the Louisiana State Police for access beyond roadblocks. Similar requirements exist in Mississippi, where the state EOC is located in Jackson."

+ NORTHWEST HARRIS COUNTY (TEXAS) ARES

From Hal Merritt, KD5HWW, EC, Northwest Harris County (Texas) ARES: "I have a few moments to breathe and share some notes. We have three running missions: a deployment near Slidell, an operator in New Orleans, and the local event.

The local mission consists of serving the mass shelters in Houston. We saw rapid escalation, much more misinformation than information, and a dynamic situation. The core problem was one we've never seen before: We had trained and drilled on mass evacuations, but not the reverse (mass incoming evacuees). Our local resources were quickly overwhelmed, and I pulled the trigger on our MOU with surrounding county ARES groups. I am now tasking hams from several counties, but may be expanding my plea for operators statewide. The problem is that there is no lodging of any kind to be had. Every hotel and motel is completely full with evacuees.

There is ample local infrastructure, except housing. The event is running along the FEMA ICS (Incident Command System) and UC (Unified Command) scripts. It may seem like chaos to the untrained eye, but it is a thing of beauty to see it working so well.

Normally, an ARES response team would report to, and be tasked by, the Liaison person of the FEMA Command Staff. There, it might be used as an ICS resource or tasked to Logistics for assignment to Task Forces or Strike Teams. Amateur Radio is not yet an official FEMA Resource Type, but that is being worked on. In this event, the Harris County OEM called us. The EOC is attached to ICS under Logistics, and that is how we fit into this event. The ICS is on site at the Astrodome complex.

The ARES response has two locations. The first team is situated with the EOC, providing communication for logistics (resource scheduling and support of the Dome team). They are making entries into a master event log, also.

The main effort is in the field, however. We have teams of four to six operators. There is a Team Leader who is in charge. He/she is responsible for on-site task assignments and for getting the relief team quickly up to speed. The Team Leaders are ARES AECs, or other amateurs with large public service event experience.

We are running six-hour shifts. No one is scheduled for more than six hours, and they have only one shift per day. Having seen what happens when someone gets too tired, we would rather do without, than have someone get hurt; or worse, get other people hurt. Superheroes

need not apply.

The ARES leadership is focused on coordination. Every possible task is being delegated. Although we are working 12-hour days, the real action is with the Team Leaders and Net Controls. No, things are not being done exactly like we would have done it, but it is getting done; and generally, with the highest degree of professionalism. Every time I screw up, there seems to be a number of folks there to beat me up and get the job done right.

Please relay my deepest gratitude to all that have stepped up to the plate. - Contact Hal Merritt, KD5HWW, at <hal.merritt@worldnet.att.net>

+ HILLSBOROUGH (FLORIDA) OPS DEPLOYED TO MISSISSIPPI MAKING A DIFFERENCE FOR KATRINA SURVIVORS

Six trained communication volunteers from the Tampa Bay, Florida, area (sponsored by the Hillsborough County EOC) have been in Mississippi. Using ham radio while awaiting their deployment with state of Florida communications assets, they became one of the few outlets for "I'm Alive" messages out of the area. With local operators in the affected area providing communications to local police, fire, and search teams, there has been limited means of transmitting H/W messages from the victims to their families outside the disaster zone.

Members of the Hillsborough team have been visiting shelters and feeding stations collecting messages from victims. More than 100 messages have been transmitted from Gulfport to Tampa via the Tampa Amateur Radio Club, and local hams in Tampa have been making heart-breaking phone calls to loved ones across the country who had no word for a week on the fate of their family members in Mississippi.

The official mission of the Hillsborough team is to set up and operate EDICs (Emergency Deployable Interoperable Communications System), a fly-away computer-controlled communications system that interconnects radios and cell phones of different frequencies and types so that public service communication can be restored in a disaster area. It allows the radios that survived to be put to use so that police officers and firefighters can better coordinate recovery operations.

The EDICs unit may be tasked to Stennis Space Center in Hancock County, or to Keesler Air Force Base, Mississippi. The team is to deploy with Florida law enforcement teams staged in Gulfport. -- Pete Kemp, KZ1Z, West Central Florida Section PIO

Gary Sessums, KC5QCN, member of the Hillsborough team writes: "Thanks for the mention in the ARES newsletter about the Hillsborough County ARES/RACES deployment. We are on site in Biloxi and Gulfport, Mississippi. We have passed over 100 H/W messages in addition to our

public safety tasking. We are on the MARS, CAP, and SHARES nets, in addition to Amateur Radio. I am trying to arrange relief for the local ARES/RACES operators at the Harrison County EOC, as those guys have been running non-stop since before the storm hit."

+ INTEROPERABILITY TIP

Watching in frustration at the breakdown of communications in the Gulf coast response, I was made acutely aware of the viability of Amateur Radio in terms of interoperability. We have the ability to change frequencies in our radios to serve the location and needs of the area.

Mobile HF, VHF and UHF radios can be re-programmed on the fly. With that in mind, one of the necessary contents of anyone's "grab and go" equipment should be the manuals, or copies of specific pages, for any radio they carry with them.

I also write down the necessary steps -- and only the necessary steps -- to program and use the radio away from the manual. I word process the steps small enough so that I can laminate them as part of my credentials lanyard. As a backup, I put another credit-card-size laminated copy in a wallet that I keep separate in a coat pocket or in the cargo pocket of my trousers. -- Chuck Heron, KD7BWG, DEC, Gila County ARES, Arizona, Executive Officer, Gila County EMCOMM (ARES/RACES), <kd7bwg@arrl.net>

+ ON RESPONDER FATIGUE

From Fred Leif, W6WTI: Thank you for putting out the special edition ARES E-Letter. It is important that hams outside the impact and support areas have a sense of the service that is being provided so that we can help explain to our neighbors and the public the vital role that Amateur Radio is playing.

Amateur Radio serves best while the communications emergency exists. The full response and recovery from Katrina will take a very long time, but when the response agencies and recovery teams have established networks that meet their communications needs, the hams should be allowed to stand down. It will be difficult to determine when this occurs, but the ARES leaders should keep an eye on this ball. We don't want "responder fatigue" to the extent that we can't get operators for the next event. Bringing our service to bear on the communications emergency, and recognizing when it is time to step aside is a vital management function.

+ DIGITAL OUTLETS

Louisiana SEC Gary Stratton, K5GLS, reports "We now have digital (Pactor/Internet/WL2K) outlets for H/W traffic into the areas noted below in Louisiana and Mississippi. National Traffic System (NTS) traffic can be sent to <ae5v@winlink.org>. At the point that destination traffic handlers feel they can take on all comers, the

directions to reach them will be shared. Louisiana towns and parishes: St. Tammany, Abita Spring, Covington, Folsom, Lacombe, Madisonville, Mandeville, Pearl River, Son, Slidell, Tangipahoa, Amite, Hammond, Independence, Kentwood, Ponchatoula, Roseland, Tangipahoa, Ticfaw, Terrebonne, Houma, Washington, Angie, Bogalusa, Franklinton, Varnado. Mississippi Towns: Gautier, Ocean Springs, Pascagoula. - Relayed by Benson Scott, AE5V

+ BRIEFS:

The Ohio Single Side Band Net (OSSBN) was to announce that H/W traffic will be accepted. OSSBN Net Manager Connie Hamilton, N8IO, who is also an Assistant Section Manager, said conditions have changed, allowing for a reasonable chance of traffic getting delivered. -- Joe Phillips, K8QOE, Ohio Section Manager

+ HURRICANE KATRINA HF RESPONSE AND RECOVERY FREQUENCIES

The following frequencies and links are the courtesy of John Mayger, W4DJ. As far as net activity is concerned, I've been listening primarily to the Gulf Coast ARES Net on 7285 kHz, and the SATERN Net on 14.265 MHz, although I'm sure there are many other active nets. Good propagation to the Florida east coast from those two nets have allowed me to monitor their excellent, professional work. - K1CE

+ FINAL NOTE AND PREDICTION

This special edition is released on the anniversary of the September 11 bombings that changed all of our lives. As with the humanitarian ARES response, then, it has been a privilege to monitor the incredible ARES response to the current catastrophe. Bravo to you, the ARES field activists.

It was also inspiring to see Newington and other staff give up their holiday and other time to support the ARES effort. Bravo to them -- they are members of the HQ staff for all of the right reasons.

And now, the prediction: When the curtain is finally drawn on this calamity, you will see Amateur Radio and ARES written -- or re-written -- into a host of more governmental and non-governmental organization plans for the future. Guaranteed. Mark my words on that one. Get your pens ready. - K1CE

I see no such reference, I see a reference that mean that but it is not
clear what type of car or HT radio. Had this been Sanagamon
County(springfield IL area) or here (houghton County) the police and

fire systems can operate autonomouslys of the 800 MHZ system not as
well

> Not to mention the comment of

> John, N9JG
==========

It makes good sense. Depending on your resources there will be mechanical problems to solve. The weight of the large value, motor-driven tuning capacitor, plus that of copper pipe will need supporting. Plastic guy ropes may be needed. And ideally the whole thing should be manually rotateable through 90 degrees.

Electrical comment : Do NOT cut the copper pipe to feed it at the bottom of the loop. The balanced feedpoint input impedance will be extremely small and impossible to match efficiently.

The best method of feeding is via a small loop of wire inside the main loop in the same plane. The small loop is approx 1/5th of the diameter of the main loop and is insulated from the main loop. The small coupling loop is just a self-supporting wire between the inner and outer conductors of a 50-ohm coaxial feedline and can be located at the bottom of the main loop.

Compared with main loop diameter, the 1-foot height of loop above ground is very low. Loss in the ground will be rather high. Try to obtain a height of 6 feet for a not very great improvement.

With a perimeter of 100 feet, on 160 meters performance will be about 1 S-unit worse than a 1/2-wave dipole. On 80 meters performance will be about the same as a full-size 1/2-wave dipole at the same height.

The perimeter is too long to work on 40m.

Further performance details can be obtained from program MAGLOOP4 from
website below.

428. Typical Leakage Calculation

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-12 00:11:16 UTC
From: "Wayne P. Muckleroy" <wmuckleroy2@neo.rr.com>
Message-ID: <EI3Ve.8446$ib1.6720@tornado.ohiordc.rr.com>
Source record: 70824

The RF power at 2W is about +33 dBm. The cable's connector ends are the most likely place for RF leakage to occur, as it is with the termination's connector. Suppose the leakage is 80dB. That would make the radiated power:

P = +33dBm - 80dB = -47dBm
(This is right at the connector site.)

The field intensity goes as the reciprocal of the radius squared. Since -47 dBm is about 20 nW and power in Watts implies MKS units,

P (at 100 feet) = 20 nW divided by (30)squared,

since 100 feet equals approximately 30 meters.

This is about 20 pW or -77dBm.

A good receiver can detect down to -120 dBm (I think).

The field strength of -77 dBm is well within the sensitivity of a good receiver of -120 dBm.

The short answer is that to detect signals 100 feet away is a likely event with a typical termination load.

Thanks a lot for your advice. I would like to use the loop on 80 meters also, but I thought that the self-resonant frequency of a 100 feet perimeter loop would be too low for the loop to be resonated on 80 meters with a series capacitor.

Also, from reading some material in the ARRL 20th edition Antenna Book, I noticed that Ted Hart, W5QJR, used a gamma-matching arrangement to feed his loop. If a small interior loop is used to feed the main loop, are capacitors needed to couple the coax feed line to the small loop? Hopefully, these capacitors would not need to be changed after the initial setup procedures have taken place.

John,

The highest operating frequency of a magloop occurs when the tuning capacitor is set to minimum or zero and the circumference of the loop is approximately 1/2-wavelength. That's rather obvious.

100 feet circumference = 30 metres. So greatest working frequency is 150 / 30 = 5 MHz.

A small coupling loop is far and away the best method of feeding a magloop. Nothing could be mechanically more simple. There are no additional components and the loop is isolated from the main loop. Furthermore its diameter for a good impedance match to 50 ohms tends to be independent of operating frequency. The wire diameter of the coupling loop need be no larger than that of the inner conductor of the coaxial feedline to which it is connected.

I've never heard of Ted Hart. But, of course, a gamma match will work. However the direct connection to the main loop unbalances it and encourages radiation from the feedline. In comparison with a small coupling loop it is also mechanically complicated.

433. best HF antenna system next to a trailer?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-12 06:07:39 UTC
From: eternalsquire@comcast.net
Message-ID: <1126505259.234971.15970@f14g2000cwb.googlegroups.com>
Source record: 70729

Hi,

I'd like some advice for determining the best antenna to put up in my situation.

I am getting set to move to a trailer park in northeast arizona, about 50 miles west of Gallup, NM. Locals have no objection to antennas so long as people don't have to run into them via normal passage ways. The trailer is 12 feet high by 15 feet wide by 50 feet long, facing N-S. Nearest certain ground is electrical panel. The water pipe is metal but could be interrupted throughout system by PVC. There may also be significant noise from AC systems in park.

Good news is that my wife is giving me an entire walk-in closet for my station, and that I can lay aluminum foil against all surfaces to create a Faraday cage.

I have approx 25 to 30 feet between my trailer and neighbors, and a 35 foot altitude streetlamp 6 feet away curb. Soil conductivity is red clay, extremely poor. Significant rainfall (monsoons) summer to fall. Winds gusting to 50 or 60 mph during winter. Soil frosts between October to March.

I would like to work CW DX on 40, 30, 20, and 17 meters. 80 and 160 would
be a bonus. Conventional options such as tower or surplus telephone pole are out of the question due to cost and lack of available area. Radials must be buried as children are playing nearby.

Probable options:

1) Load up the streetlamp with an antenna matcher, work against 180 degrees of buried radials out to 1/8 lambda.

2) Solder a series of tin/steel cans (cantenna) using pocket torch and copper tape to 1/4 lambda with added capacitance hat(s), brace the cans against the ground and the trailer, work against 270 to 360 degrees of buried radials out to 3/8 lambda.

3) Create a mast from 40 feet of metal pipe and 15 feet of wood rod, brace against trailer burying pipe end 10 feet, mount an inverted vee trap dipole in N-S direction for E-W DX.

4) Pair of masts on either side of the trailer, mount a delta loop from each mast, feed one loop and use the other as a reflector.

5) Pair of cantennas on each side of the trailer, operating as out of phase pair of 1/4 lambda verticals.

Which would be best? And where do I place the lightning arrestor(s)?

Thanks,

The Eternal Squire

Thanks again, Reg. You can be sure I am printing out your comments and
storing them in my loop project folder. I will also be perusing your web
site http://www.btinternet.com/~g4fgq.regp/
I will need some info on size and placement of the coupling loop.

Regarding Ted Hart, W5QJR, there is some information about him at
http://www.nab.org/conventions/radioshow/2003/participantbio.asp?id=10459
A Google search on Ted-Hart Loop-Antenna finds about 100 hits.

Source record: 70738

If you have constructed a digital wattmeter based on one of the Analog Devices AD8307 logarithmic amplifiers you can probably easily interface it to a PC. The design by OZ2CPU on http://www.webx.dk is capable of this and the software in the PIC sends a continuous stream of power readings in tenths of a dB to the serial port.

PolarPlot V3.1 (http://www.g4hfq.co.uk/plphelp/plphelp.htm) can now use these power readings to plot the radiation pattern of beam antennas.

The advantage over the previous method using a sound card is that much better resolution can be achieved at levels lower than -35dB. In addition it is easier to set up levels and there is no more battling with the Windows mixer application or the RF gain of your receiver to get the audio level correct.

V3.1 of PolarPlot still supports the sound card as well as the OZ2CPU wattmeter. A purpose-built wattmeter is being designed and programmed by M0DFT.

How would the park owner feel about that? 1/8 lambda of what? 80M?

>2) Solder a series of tin/steel cans (cantenna) using pocket torch and
>copper tape to 1/4 lambda with added capacitance hat(s), brace the cans
>against the ground and the trailer, work against 270 to 360 degrees of
>buried radials out to 3/8 lambda.

Sure, it's been done, but more as a gag because so many simpler
options are available. It will need just as much guying as the next,
more conventional vertical anything. So why not just go out and get
that some nested tubular sections? Army surplus field antennas 40
feet high have been selling for $80 - $100 for years. And they come
complete with even the sledge hammer to sink the guy pegs.

>3) Create a mast from 40 feet of metal pipe and 15 feet of wood rod,
>brace against trailer burying pipe end 10 feet, mount an inverted vee
>trap dipole in N-S direction for E-W DX.

Ah! 40 feet of metal pipe. Glad to see that the stack of cans has
an alternative. Well, this is a start for testing various designs
against.

>4) Pair of masts on either side of the trailer, mount a delta loop
>from each mast, feed one loop and use the other as a reflector.

An elaboration of the 40 feet of metal pipe.

>5) Pair of cantennas on each side of the trailer, operating as out of
>phase pair of 1/4 lambda verticals.

Dump the cans and stick with the 40 feet of metal pipe. But it seems we got here by wanting an antenna that worked most the bands. The "phase pair" is not that and it will probably have more effort involved than perceived return. Certainly that is something that never stopped anyone who starts this kind of project and it will offer hours of diversion.

>Which would be best?

The one with best DX. You could as easily ask which would be:
the easiest, efficient, practical, useful;
or to go with the antonyms:
the absurdest, illogical, impractical, tortured....

It all depends on wavelength and the terms flip from one category to the next, appropriately.

Overall, the longest dipole you support as high as possible, with a twin line transmission line to a tuner. Add a ground field so you can tie the transmission line together to drive it against the ground for the lowest band.

>And where do I place the lightning arrestor(s)?

As close to your ground field as possible (with it, in turn, tied to the ground of your panel per code) or you will become the Eternal Flame.

John,

In principle, the coupling loop can be located in the same plane and anywhere within the main loop. So it is most convenient to locate it at the bottom of the main loop within an inch or two of the main loop.

But make no direct connection between the two loops or between the coax and the main loop. There has to be some sort of support for the coax and coupling loop. So you can make use of the insulating jacket of the coax feedline and sticky insulating tape. If any other supporting insulating materials are needed any plastics will do.

You can, of course, make a beautiful engineering job out of it which you can be proud of. But, radio-wise, the antenna will not work the slightest bit better. ;o)

A comment about a motor-driven variable capacitor at the top of the main loop. To allow the main loop to maintain self-balance about ground, insert a multi-wire choke in the control wires and any other wires feeding the motor. Or whatever form the motor may take.

Remember, the main loop should be allowed to take up its own natural balance about ground to reduce "radiation from the feedline."

In the case of magloops, radiation from the feedline is a matter of loss of radiation from the antenna. Waste not, want not!

I have listed a NEW SGC SG-230 SmartTuner on ebay. As you most likely know, this is the ultimate automatic antenna tuner.

This is a commerical grade, state of the art antenna tuner for Ham, commercial, marine, aviation, military, intelligence and shortwave use.

For more information or to see the pictures click on this link:

http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=6802005559

If the linik does not work for you, just go to http://ebay.com and do a search for: "SGC model SG-230"

I have the ability to ship this unit worldwide.

Thanks,

Bill

Hi all,

I am thinking of building a full wave loop for 17 meter ham band. What I plan to do is to build a cross shaped form...then run wire approx 12.7 ft on each side....then hang the antenna vertically from a tree or mount it on a support 30-40 ft up with the V point of the antenna straight up with the other "V" point straight down. In other words the antenna will look like a diamond hanging vertically in the air. If I feed the antenna at the bottom V with ladder line, one lead on each leg, how will this antenna perform? The antenna wire wil be seperated at the bottom point-not tied together. Will it have any gain? I am sure there will be directivity broadside to the antenna.Thanks for any help.

Not over a dipole at the same maximum height.
Lots of gain over a 1/4WL vertical. :-)

450. Balanced from unbalanced via a 100 ohm Q section

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-12 20:39:23 UTC
From: Bob Bob <bob3bob3@cox.net>
Message-ID: <rk5hv2-2i4.ln1@p400bob.personal.cox.net>
Source record: 70747

Hi all.

Throwing together a 20m single quad loop (triangular) antenna. In the past I have fed these with a 75r Q section. Nothing strange here.. I use to coil up most of it in a 5" coil to help reduce the line radiation problem - if any... No tuner in use..

This time however I am going to use two pieces of 50 ohm coax in parallel giving a 100r balanced Q section feeder. This more closely matches the loop Z. The shields are joined together at each end of the section and the coax centre conductors become the two antenna connection points.

Question;

Should I be worried about inbalance in the 50 ohm cable from the radio to the Q section. ie does the Q section reduce any of that problem? If that isnt the case I can make up the usual coil of coax before it meets the Q section.. or can I coil up the Q section instead.

I also wonder about Q section shield grounding as I hadnt intended grounding either end. Will this be an issue?

Cheers Bob W5/VK2YQA

Mine packed up. Four years of pactor email did it.

Apply RF power and the relays chatter never settling down to a tuned configuration. It does this regardless of whether I am trying to load up an antenna or a dummy load.

We have been playing with PIC's lately. I wonder if it is worth while to use a PIC and the relay switched inductors and capacitors to make a make a home brewed automatic tuner. PIC frequency counter software is all over the net. Something like a 16F870 has five 10-bit A2D's. That's about all one would need to make an automatic tuner from a broken SG-230.

I have a question, Why?

The loop Z is going to be in the neighborhood of 120 ohm. A 75 ohm Q
section is a better deal than 100 ohm.

Bob:

My math says that 2 sections of 50 ohm coax in parallel makes a 25 ohm feeder, not a 100 ohm feeder. Also, if your intention is to use the 2 coax center conductors to connect to the loop feedpoint, where will the differential mode currents which are necessary at the feedpoint come from? And if you don't connect the coax shields to something at the feedpoint, where does the current flowing in the shield go?

Your idea sounds something like the DK7ZB match for yagi antennas: http://www.qsl.net/dk7zb/dk7zb-match.htm It allows matching the approximately 12.5 ohm feedpoint of a yagi to be matched to a 50 ohm feedline. Note that the coax shields at both ends of the Q section are connected to something.

The modelled Z is around 140 ohms. The "top" element of the loop is about 20% longer than the other two. It is starting to approach a folded dipole.

Hi Roger

Okay bad choice of words. Try series... With the centre conductor of
both coaxes joined at each end you do indeed get 25 ohms.. "Parallel"
was more a case of describing the physical rather than electrical layout.

When you connect just the shields you effectively have a 100 ohm
balanced but shielded feeder with the two centre conductors being the
"real" transmission line. Also apparently good for placing inside a
metal pipe without it affecting the transmission system - but I am not
doing that.

And where the 50 ohm coax from the radio joins the bottom of the Q
section its shield goes to one wire and the centre conductor to the other.

Okay?

My experience with an LDG Z11 has been very much unlike that. They make several models, including one that will handle a kilowatt. The Z11 I have was intended for QRP with a maximum of 60 watts. I can't tell you how the other models will work, but they are all based on the same microcontroller (I think) and base software, so my guess is that they will perform equally well.

I bought my Z11 as a kit, and it was a well done one. As good as any Heathkit. Doesn't look like they sell kits any longer.

The web site is www.ldgelectronics.com.

FS: shortwave radio dx-394

this is a radioshack all digital shortwave reciever.
covers 150 khz to 29999 khz
am,usb,lsb,cw bands

digital green backlit display.
programable stations, s-meter

this is a well cared for reciever that i have used
and owned for many years. it will operate on 12 volts
or 120 volt ac power source.

has a telescopic antenna (factory)
or you can thread on a pl-259 coax connector
(c.b. radio type) and use an outdoor antenna.

has a tape recorder rca connector on the back
for recording broadcast. or you may use this
to link to your computer with the right software
to decode morse code and weatherfax's in real time.

I would like to get $75.00 CA
for this reciever, not including shipping..

remove NOSPAM from my email address to reply.

They finally backed down today, after a change in the HOA and a
number of residents calling realtors to see if they could find another
home to move out of Majestic Oaks.

BTW, the same HOA tried to evict a resident after 9/11 for having the
nerve to display the American flag in one of their windows. The local
paper had printed a full page American flag on heavy paper stock and
asked people to display them in their homes.

Hi Steve,

The clssic Quad loop is a good single band antenna , you could feed it
with coax as well. (75 ohm) The impeadence is about 125 ohoms. It will
have on the order of about 1 to 3 db of gain over a dipole
bi-directional. but that is not much and you won't notice a lot of
difference , some claim the loop is much quiter on Rx and that has been
the experience here. If your thought is to use it on multiple bands the
vertical loop is a poor choice for that application.. but it's a good
single band antenna.
you may want to look over the material on Cebik web page at
http://www.cebik.com/fdim/fdim5.html

In any event have fun and experiment.

468. Help required to identify antenna type

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-13 11:54:03 UTC
From: David <groups@orbitcoms.com>
Message-ID: <v5zVe.42161$FA3.13896@news-server.bigpond.net.au>
Source record: 70765

Hi,

I have a Whip antenna that is supposed to give 3dB "gain" at 915MHz.
After pulling the unit apart and studying the construction, I am not
sure what style of antenna this is.

The antenna consists of an SMA plug that has RF178 cable soldered to
centre pin and
it appears earth braid is connected to ground side of plug.

The cable goes up the inside of 1 6mm Nylon tube for 40mm and then
exits the tube and winds around 4.5T. It then enters the tube
again and runs another 80mm. At this point the earth braid is stripped
leaving only the centre conductor and dielectric to continue another 70mm
to the top of the Radome (Nylon tube).

I understand the construction of 5/8 antenna but I would not expect the
braid to be earthed.

Thanks in advance for any help.

Regards

David

the 4.5 turns is a choke that cuts off the bottom part of the braid from the top. the top 80mm and 70mm parts are then just a vertical dipole with the feedpoint at the spot where the braid stops.

there are programs that will calculate it, but usually not very accurately.
it is best to measure it and either adjust it to match the feedline or add a
matching network to get it to match the feedline. how closely it must match
the feedline depends on what it is being used for, which you haven't said.

Judgments!!! Would it not be better to read the exact terms of the CC&R,
AKA CONTRACT, before judgments are made??

The exact wording of the HOA/CC&R may restrict certain activities [such
as external antennas, or temporary housing, etc]. The restriction can
only be waived by consent of the members of the HOA.

Impedance is very complex. As mentioned in another reply the easiest way
is to measure it. But, that post did not give advice on how to measure it.

Contact a Ham [amateur] radio operator/station in your area. Once found,
ask if [s]he knows someone who has an antenna analyzer. Most Antenna
analyzer owners, they cost about $200 to $300 USD, are willing to make
the measurement for you. Most Ham clubs have several people who own such
instruments.

What kind of antenna did you build? If it is a 'standard' type we can
give you a fair estimate right here on r.r.a.a.

There are more formulas than there are types of antenna.
Please describe in little detail the type of antenna you are
interested in.

But in general, you will be unable to use a formula because you will
not know the basic data to put into it.

However, given more information, somebody may be able to provide you
with a sufficiently accurate numerical value.

Reg.

The two sections are not electrically paralleled but instead
are used as balanced feeders. They are physically parallel
but electrically in series, thus Z0 = 100 ohms.

If you describe it, some kind soul may be able to tell you.
Is it single frequency or multi-band? Sometimes a 1:1 choke
is the logical choice for a "balun".

What a lot of us do is model our antennas to get an estimate
of the feedpoint impedance. A free version of EZNEC can be
downloaded from http://www.eznec.com.

Other free software available from:

I purchased these a while ago and pulled them apart to see if there was
much involved in making similar units. They stated 3dB but did not
indicate whether it was dBi or dBd.

What are your recommendations for 915MHz omni-directional antenna ?
I want to see what kind of range I can get from a pair of 1 Watt,
spread spectrum data transceivers with oni-directional antenna.

Thanks

Hi Roger

Might get around to it today! (Being unemployed is sometimes fun..)

Also looking at the possibility of harmonic operation w/out adjustment.
Not useful for a 20M quad as the next usable freq is about 38Mhz. I
found though that if I (modelled) cut for 10.1Mhz it is also usable
28.4-29.0. This is also a good reason for using the high side impedence
transformation (ie 50r to 100r = 122r vs 50r to 75r = 90r) as the Z on
10M is higher. Radiation pattern isnt much good for long DX though..

Cheers Bob

No phasing coils anywhere?

> What are your recommendations for 915MHz omni-directional antenna ?

I'm not the person to ask. All I would do is access the
web pages of the antenna manufacturers, like Diamond.

It is exactly that type of over zealous HOA that made me tell my Realtor, "Do not shot me a house with any HOA!" On our first trip out , the first house she showed me had an HOA. I told her, "If you do that again, you are fired" She looked shocked and said, "It's only $50/month." And I replied, "It has nothing at all to do with money..."

Of course, now I have a house across the street with no less than 8 cars in the driveway and street. So much for single-family-home. But, we all get along.

Carl

SQRT(50*140) = 84 ohms. Z0=75 ohms is closer to
84 ohms than is Z0=100 ohms. If you had a 200 ohm
feedpoint, Z0=100 ohms would be perfect.

Source record: 70684

Eternal Squire wrote:
"I`d like some advice for determining the best antenna to put up in my situation.

I am getting set to move to a trailer park in northeast Arizona."

Phil Rand, W1DBM distilled 35 years of trailering experience in QST and it was reprinted in the 1978 ARRL Antenna Anthology.

As Richard Clark wrote, there is no miracle antenna.

Phil found a simple dipole only a few feet above ground would outperform a mobile whip on 40 or 75 meters.

Here is Phil`s Table 3:

Hustler 75-meter Mobile whip mounted vertically on top rear corner of trailer-------S7

Same as above with 60-foot counterpoise connected to trailer-----------------------------S9

Two Hustler mobile whips back to nack
as a horizontal loaded dipole-------------S9+5dB

60-foot horizontal wire 8 feet high using trailer (30-ft. Airstream) as ground------S9+10dB

Hustler 4BTV trap vertical with
75 meter resonator-------------------------S9+10dB
120 foot dipole, 15 feet high at
center---S9+20dB

Airstream Loop antenna------------------S9+20dB

Home station dipole 50 feet high------S9+30dB

Feet = 0.3048 m

There is a lot more in the article which may interest operators from trailers, but I`m not a typist. Check the Airstream Loop antenna. Nothing extends laterally from the trailer to trip anyone up.

Best regards, Richard Harrison, KB5WZI

487. 73 Ohms, How do you get it?

I am a newbi in antennas.

Here's my question:

I know that a half-wave dipole in free space has
a feed-point impedance of approximately 73 ohms.

Can anyone tell me **exactly** how this number is calculated.

(or tutorial webpages)

I mean I like to see a general formula (a function of
antenna height above earth....) and all the detailed steps
that will get the impedance number.

Thanks!

-- Harry

John,

I once had a magloop for 160 and 80 meters almost as big as the one you propose. It worked fine. According to predictions. Eventually, needing the garden space for other projects, I swapped it for a bottle of New Zealand white wine.

But to reduce the weight of a 1.5-inch diameter copper-pipe conductor plus the tuning capacitor, the conductor was made of thin-wall, hard aluminium alloy known as Duralumin in these parts. (Pure aluminium is far too soft and is useless.)

The loop was formed from three sections of tube which fitted into each other to make a complete circle. The curvature of the sections had to be formed in an engineering workshop.

It needed three guy ropes and could be rotated about an angle of 90 degrees, five feet above ground level, inside a 2-inch diameter, cast iron tube sunk into the soil.

There was an aluminium alloy vertical supporting tube which extended from below ground level almost to the highest point of the main loop and the motor-driven tuning capacitor. A vertical conductor, running diametrically across the main loop, has no effect on electrical performance.

I had very good neighbours. Never had a single compaint about the wierd contraption which soared well above the skyline from my side of the 6-foot high bushes and trees which constituted the boundary between my property and theirs. It never occurred to me to request planning permission from the local authorities. With the assistance of a local Black Country radio friend, G3VFF, a born mechanical engineer, handicapped by an industrial accident, we just erected it!

It helped, to my satisfaction, to prove the veracity of some of my radio software programs.

John, I wish you all the very best with your project.

Cheers, Reg, G4FGQ.

Cecil already gave you the answer. A 90-degree line is called a
"geometric mean" transformer.

The required impedance is the square root of the product of the
desired R and the load R.

Here's a little tutorial:

http://www.microwaves101.com/encyclopedia/quarterwave.cfm

That calculation comes about as the culmination of a two-semester junior-level college course in Electrodynamics. Because of their mathematical intensity most people suffer through such courses with grim determination rather than greeting them with joy.

The 73 ohm number assumes an antenna in free space with a magic zero-size current source at it's center and no wires going to the antenna. Then some handwaving simplifications are made, a current gradient is assumed, a voltage gradient is calculated, and the impedance (and antenna pattern) is calculated. If you want to avoid the handwaving simplifications you take _another_ year of antenna-specific E&M and/or you write a program like NEC to do the calculation numerically.

This is why the antenna chapters in the Handbook start with very basic theory then take a very long jump to a compendium of results, without trying to fill in all the space in between.

~~~~~~

Without more information, this comparison is flawed. A mobile whip has a lower angle of radiation than a horizontal dipole. On 40 or 75, the vertical component of radiation can be quite significant for close-in stations (100 miles or so). At night, working long distances, the whip may outperform the dipole. During the day, the dipole will probably outperform the whip.

It all depends.

I chose an older neighborhood, and, like you, I refused to accept any HOA bullcrap. I simply will NOT tolerate any old blue-haired busybody telling what I can or cannot do on my own property! IOW, yer rights end at that property line, and if you don't like what I do then come over here and *make* me do something about it--all 6 feet, 230 lbs of me!!! :) Now to clarify something, all my neighbors are nice people who keep their homes and property looking decent. If there are 2-3-4--or 7 cars over there, it ain't none of my business! So we have no problems. (and I get to put up as many ham antennas I want to!)

Source record: 70688

Phil found a simple dipole only a few feet above ground would
outperform
a mobile whip on 40 or 75 meters.

NVIS sure...Wouldn't be so sure about long haul... My 40 meter
mobile beats my home dipole at 40 ft on a 1000 mile path.

Here is Phil`s Table 3:

Hustler 75-meter Mobile whip mounted vertically on top rear corner of
trailer-------S7

Part of the problem...His mobile is stunted... :(

Same as above with 60-foot counterpoise connected to
trailer-----------------------------S9

Two Hustler mobile whips back to nack
as a horizontal loaded dipole-------------S9+5dB

Again kinda stunted due to the lousy hustler coils... :(
Could be better than that if better coils were used.

60-foot horizontal wire 8 feet high using trailer (30-ft.
Airstream)
as ground------S9+10dB

Pretty mediocre if NVIS...

Hustler 4BTV trap vertical with
75 meter resonator-------------------------S9+10dB
120 foot dipole, 15 feet high at
center---S9+20dB

Airstream Loop antenna------------------S9+20dB

Home station dipole 50 feet high------S9+30dB

Sounds like these are all NVIS paths... For those,
I agree, a dipole/loop is usually best. One problem though...
Often when mounting a low dipole next to a large metal trailer, etc,
the coupling often will make tuning quite difficult. I'd try to get
the dipole as far away from the trailer as possible *if* it
acts squirrely... But a *good* mobile antenna could often
be quite good to longer hauls. On the higher bands, a good
mobile antenna should be just fine.
If it were me, I'd #1 run the best mobile antenna I could rig up
as a vertical. Then I'd run a dipole for low band NVIS stuff. In my

case, I prefer paralleled multiband dipoles, at right angles, but
if I can only run one wire, I'll make a multiband dipole split
up with clipable insulators. If thats not workable, I suppose a
trap dipole could be used, but thats always my last choice
for a multiband dipole setup, being I like every drop of
efficiency I can muster. But the losses with those is not that bad.
With my mobile antenna, I could easily use *just it* if I wanted,
on any band. But my mobile ain't no stunted hustler antenna.
When I'm parked, my usual coil position is higher than the total height
of the average hustler whip. My mobile eats hustlers for lunch
and spits out the seeds... :) It's ugly. I did some tests using
hustler coils
vs my usual homebrew...Wasn't pretty... Adding the hustler coil
is like turning the antenna into a dummy load, *even* considering
that in most mobile setups, ground loss overshadows coil loss.
So if you see a *drastic* decrease in perfomance when changing
coils, Houston, we have a problem. I've seen many claim the "small"
hustler coils are actually more efficient than the "super" coils, which

was the type I tried. Luckily , I didn't pay for it, and I gladly gave
it back after testing... I think he stuck it on a hustler vertical...
Poor
thing.... :(I'd forget the "can" antennas, etc...A good mobile whip
would
likely do about as well. I'd use wire, or regular masts to make a tall
vertical. To me, cans sound like a soldering nightmare... :/ MK

Simple Ohm's law: If you apply 73 volts of RF, 1 amp of current will flow.

To calculate the effects of nearby ground a program like EZNEC is useful, although you almost never know the exact parameters of the ground, so the results should not be taken as precise.

Gerry, you said it correctly. Tell your agent "I will not consider, under any conditions, any HOAs or CC&Rs." If the RE attorney uncovers any 'hidden' CC&Rs in the title search, the sale is OFF!

I live in the "Live Free or Die" state [New Hampshire]. When I bought here three years ago I made that point to our realtor. We bought a very nice single family home of 2100 square feet on a 1/2 acre only 21 years old, 6 miles south of the state capital and 12 miles north of the third largest city.

I checked town zoning requirements for a tower. I'm allowed 70 feet for the tower without requesting a variance. Also, if the tower is professionally installed I need not consult the town building inspector. Heights from 70 feet 1 inch to 200 feet require plan approval by the building inspector ONLY for safety issues. BTW: my tower is only 50 feet [I live on top of a 510 foot hill with height above average terrain of 250 feet for 5 miles radius].

But back to the original issue. The HOA may have a strict rule on temporary housing. It is a freely entered into contract condition that requires the consent of the contracting parties to amend.

So, the term 'BIGOT' is a prejudicial pre judgment.

> Hi Dave, I'm interested in knowing how you get the gain of a
> quad loop to equal the gain of an Extended Double Zepp dipole?

Hi Cecil,

Good Question.. I should have been more specific.. the gain of a fullwave vertical loop over a 1/2 wave dipole is approximatel 1.2 db-- if you use the same antenna on the 2nd harmonic you will get about 3 db gain , but with that said we must realize that this gain is not necessarily at good angles for DX. The dipole may actually have a better pattern that a 2 wave vertical loop. and thus any gain achieved will be negated by the fact that this gain is at angles that are not conducive to good Dx propagation.

Cebik places the gain of a full wave vertical loop at about 5.9 dbi that rises to about 7.6 dbi on the 2nd harmonic and about 8 dbi on the 4th harmonic.

But the T.O. Angels are as follows-- Fundamental Frequency- 35 deg. 2nd harmonic 48 degrees 4 harmonic 45 degrees This is for a square loop. these are not great figures for DX but useable none the less. A Dipole would though I have not researched it do better in the angle department. thus any gain received by the loop would be negated but a stornger signal at the right angle by the dipole.

73 Dave

Often at considerable personal risk....

A guy who is a radio-tower contractor (like cell sites, microwave towers,
commercial radio stations, etc.) sent this.

We got the call on Sunday afternoon. I expected
it, of course. After 18 years of doing this I can always sense when
the call is about to come. We gathered supplies on Monday and got
out the tents, Coleman fuel, cook stove, lanterns and bedrolls. Becky
graciously went to the store for our provisions, then to the bank for
cash, and by dark we had all in order.

We went by to see the customer on Tuesday morning to equip ourselves
with radios, site maps, and lists of those that we would be reporting
to. As we departed on Tuesday mid day I knew that this would be
another great adventure. All was good through Pine Bluff and Lake
Village, Arkansas. Greenville, Mississippi was even tolerable. By the
time we got to Yazoo City, however, things had changed. No ATM's, no
gas, no ice. I knew we were in trouble when the lines at the check
cashing places were longer than those at the banks. We had half a
tank. I had stopped in Dumas and bought 12 half pints of whiskey
knowing that with such legal tender a full tank could be mine
whenever I wished. We pressed on.

We arrived in Jackson to the sight of long lines at the gas stations
and grocery stores with crowds gathered outside. How wonderful it
felt to have the secure gates of the Entergy compound locked behind
us. There was little electricity and no hotel rooms. We readied the
camping supplies and checked the map for a good state park. A little
fuel from the Gods at Entergy and we were on our way. We found a
decent park (no electricity, of course) and pitched camp. Dinner was
chicken helper, mashed potatoes and tea. It began to rain but
thankfully we had brought a huge roll of Visqueen. A large tent was
erected above our sleeping bags and in no time Wednesday morning

found us nursing our mosquito bites and eating oatmeal. After that it was off for a day in the air.

I should mention at this point that I brought my stellar lead man, Paul Fitler. Paul spends too much time in jail, too much time in the sauce, and too much time attending to women that can't take care of themselves. He is constantly deep in debt and out of a place to live, and good transportation. He is also the best, and highest paid towerdog in the state. An average week for him is $1000.00 gross. He'll easily double that during his tenure here. In fact, I'd imagine that he may have a $2500.00 week before it's all over. He has worked for me over eight years. He can't last working for anyone else more than ten days.

We take off Wednesday in a search for fuel, ice, and towers on our maps and find all of them. It is another long hard, hot day. We are constantly greeted with bewildered folks looking at trees impaled in their roofs, cars mangled and electric lines in their yards. We have Entergy signs on the side of the van at this point and when they see those signs their looks are heart wrenching and desperate. We look back with sympathy. They do not understand. They want us to have the answer. They want us to make it all better. They want relief which we cannot give. We give 100% that day and many communications tower sites come back to life. We see the line trucks begin to roll as we leave town. We are glad to have played a part in this process.

Thursday finds us in the office. The telecom crew is going ballistic. There are people everywhere barking out orders. So and so needs 19 phones installed at the office in Hattiesburg , the computers are down at thus and so, the radio system has died at Tylertown and the line crews can't work. The locals see the trucks sitting idle and they are getting angry. The locals don't understand that the line crews can't work unless they know for sure that lines are not energized.

The line crews can't be assured of that unless they have good communications. They can't have good communications unless the telecom guys do their jobs and in turn, unless we get the antennae fixed. So the locals are mad. Mad as Hell.

We listen to all of the banter going back and fourth and suddenly someone is shoving a piece of paper in my face and screaming loudly... Generating station (power plant) South of New Orleans . it's off line... no output... city is dark enough as it is... something has to be done. they need a 20 KW generator ASAP in order to have lights so they can get the plant back in service. Someone has to go. It is a war zone down there. The plant must come back to life... And then the inevitable question: "Will you go?" It echoes in my mind... Will I go? Will I? Can we take that chance? I smile. Actually, I grin. Yeah. I'll go. I give them the inevitable response to their inevitable question. "You bet your sweet ass I'll go... Press hard pal, Five copies"!!!

We top off the tank, load the shotgun, holster the pistols and hit the road. This is going to be a trip to remember. As we head out there are few cars on the road. No gas. The traffic is minimal and we set the cruise on 60 so as to conserve gas. Getting there will be easy. Getting back will not be as assured. I know, however, that we have enough gas to get to the plant and at least back to the Mississippi/Louisiana state line. I've got food, ammo, tents and lots of water. If I get stranded I'll be ok. We drive along saying little. We know that one wrong turn or wrong word at the wrong time to the wrong person could change things real quick.

With the Entergy signs on the truck we glide through every roadblock with ease. Cops don't ask for our ID or license. They don't search us. They really don't even look at us. We are riding on a magic carpet. No one will mess with us. They can see what we have in tow. Ah yes. The generator. The magic elixir that everyone wants. Generators make oxygen systems work; they bring food refrigeration units back to life; they bring light to the darkness, life to the newborns at the hospital. We have the generator. We are the stewards of all that the citizens hold sacred at the moment. We are the golden boys. They smile us and we smile back.

We get onto I-310 and then onto US 90 headed for the plant and suddenly our swollen heads and large egos begin to shrink. We are greeted by bands of wandering blacks about 15 to 20 in number. Every store front is destroyed. Some buildings are burned. All of the glass is gone from every window. We do a quick mental calculation as to wind direction during the storm. We realize quickly that many of the broken windows are on the downwind side. We see the crowds... it all makes sense then.

We get to the end of US 90 and make our turn towards the plant. We are confronted by a policeman in full riot gear. The intersection is desolate save for him. An industrial wasteland with this one shred of order standing in the road. He reminds me of some cavalryman in Oklahoma in the early 1800's or some sheriff in a town of lawless criminals. He looks over our cargo curiously and gives us a halting look, letting us know that "Entergy trucks have been taking fire in this area. I suggest you remove or cover your decals".
We see the plant up ahead. The sign of the guard lowering his shotgun is a welcome one. We make our delivery and point our truck for Jackson.

The men at the plant we visit with are worried. They don't want to risk the ride home. Some have wives and kids they must attend to. They have no choice. The others opt to sleep in their trucks to avoid venturing from the perceived safety of the 12 gauge in the hands of the guard.

I envy neither of them. Either choice is dangerous. The gangs in the streets are hungry, thirsty and angry. Neither the guard nor the men on the way home are any match for them. The gangs know it and the men know it. For the first time I understand the delicate balance between

prison guards and their charges. The criminals really do have the upper hand at some moments. Everyone just allows the perceptions to be different than that.

As we head home among fallen timbers, power lines and buildings we come across a group of cops with side arms drawn and pointed at a group of men. On the ground are 15 or 20 individuals cuffed and laying on their faces. There are 9 or 10 cops and only 5 or 6 in the crowd, save those on the ground, so we figure the cops are winning and we punch it and move on. Every store has the front doors kicked in. One shopkeeper had the brilliant idea of putting his coke machines in front of the doors to prevent entry. The thugs were offended and responded by putting a truck through the windows. After they finished their shopping they left their calling card by way of a Molotov cocktail. How quaint.

I thought we were going to burn a hole in the gas gauge on the way home with our eyes. We calculated and recalculated. Every road sign showing mileage to the next map point was checked and rechecked. We were always cognizant of the five gallon can in the back. The fumes it emanated were like sweet perfume to our olfactories. That was the sweet smell of a soft landing. We knew that we could make it back. We felt good about that.

I thought of the B-29 pilots flying missions over Japan in 1944. Their calculations were much harder and there was much more at stake. I wondered what it was like for them when they ran the numbers and the result was death. What were those last hours like? What did they say to one another? I said a prayer for their souls and paid my respects. Real men. Let me never forget that.

My air mattress coupled with the floor of the Entergy Radio shop at Jackson, MS was a welcome relief. I looked forward to a good night's sleep only to be haunted by the looks of those on the streets. Why them and not me? I guess I'll always ask that. I always have. Why am I even here? What drives me to do these crazy things? Why would I put my best lead man along with the father of my children in harm's way? I don't know the answers to those questions. Frankly, I don't really care about the answers. I'm just glad to be safe and alive tonight. I feel bad for those that are without homes and families tonight and wish I could do something to take away their pain.

I think when it is all over I may go back down to that stretch of Highway 90 where the shops were burned. I think I may go back there and meet with the owners. Yeah. That's what I'll do. I'll meet with them. All that they have worked for was taken away from them by one violent act of nature and many lewd acts of men. I'll go meet with those men and women and engage in commerce with them as I can. And when I do. I'll tell them that I understand. Because I do. And they will know that I do. And in the end. I will know that everything will be OK. And they will know that too.

There's no such value as 'exact'.

All you have to do is integrate the power flowing outwards from a dipole at the centre of an arbitrary sphere with a surface area of x square metres and equate it to the current flowing in the dipole, taking into account the distribution of current along the dipole, and you will obtain the radiation resistance referred to its feedpont. OK?

But in your case, all you can do is just accept the hearsay value of 73 ohms as being good enough.

Actually it depends on the diameter of the dipole relative to its length and at HF it is a few percent less. Not that anybody ever notices such minor discrepancies.

Reg, G4FGQ

Hi Tim and Reg,

Thank you for your valuable information. Is there any website or textbook that actually shows the step-by-step calculation of this magic number which has been quoted so often in the cable industry?

You know most video cables and connectors have characteristic impedance, 75 Ohms.

I am not afraid of math. I just like to understand the details of its derivation.

-- Harry

What you're seeking is in the book _Antenna Theory, Analysis and Design_
by Constantine A. Balanis, ISBN 0-471-59268-4.

Transmission line calculations are much easier than antenna calculations.

To a first approximation: Zo = SQRT(L/C); where L = inductance per unit length, and C = capacitance per unit length.

If a ham can only use their station "in times of great need" it's unlikely
they'd have the equipment to put into service, so it's all a moot point.

I was talking about temporarily taking in those left homeless and how it shows a lack of humanitarianism.

The equipment thing is an entirely separate issue that needs addressed one way or another as it cannot be left to the last minute as you point out.

From "Antenna Theory" by Balanis:

Rr = 2*Prad/|Io^2| = 73 ohms (4-93)

Prad is found by integrating the Poynting Vector over a
certain radius. Io is the current maximum magnitude.

The ASCII limitation prevents much more than this.

You're right, Reg. Without reflections from the ends of a
dipole, the feedpoint impedance would be hundreds of ohms.
A standing wave antenna is like a lossy transmission line
where the loss is to radiation. And the SWR on a 1/2WL dipole
standing wave antenna is quite high - in the neighborhood of
20:1.

It is equally correct to say that the radiation resistance of a dipole is 2*73 = 146 ohms, since this is the value when the radiation resistance is assumed to be uniformly distributed along its length as is the conductor resistance.

For calculating purposes the radiation and conductor resistances can simply be added together.

And when referred to the end of a dipole, at HF the radiation resistance is of the order of Q-squared * 73/2 = 3000 ohms. Although this is somewhat indeterminate because of the difficulty of feeding an isolated dipole at one end. The conductor diameter also plays a significant part.

Reg.

As someone who lives near Ocala and has to visit a lot of these gated communities run by HOAs, I find most of them to be jerks who are only interested in holding onto their perceived power at any cost. The fact that it hurts others doesn't matter to them. Another HOA in the area told a retired couple move out, or send their 17 year old grand daughter away after she lost both of her parents in an accident. She had a few months till she was to graduate from high school and no other relatives but it didn't matter to the HOA. People like that are scum, no matter how expensive their home, or what they drive.

Its just too damn bad you can't tar and feather them and then run them out of town, like the good old days! ;-)

518. Re: 73 Ohms, How do you get it?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-14 00:47:09 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <11iesohk2gnkf80@corp.supernews.com>
Source record: 70715

Just about any antenna textbook will show you the calculation of a half wavelength, infinitely thin dipole in free space. For that special case, the answer ends up being simply 30 * Cin(2 * pi), where Cin is a modification of the cosine integral Ci[*]. That's where the "magic number" comes from. Kraus' _Antennas_ is just one of the many textbooks which give the derivation for this. It takes about 3 pages and 23 equations for Kraus to derive.

One assumption made in calculation of this value is that the current distribution is sinusoidal, an assumption that's true only for an infinitely thin antenna. For finite thickness wire, the calculation becomes much more difficult. The radiation resistance changes only slowly with wire diameter, however, so sinusoidal distribution is a reasonably good approximation provided that the antenna is thin. Feedpoint reactance, though, varies much more dramatically with both antenna length and diameter. Calculating its value exactly requires solution of a triple integral equation which can't be solved in closed form. That's why computer programs are used to solve it numerically.

To include the effect of ground, you need to calculate the mutual impedance between the antenna and its "image". If the antenna is about 0.2 wavelength above ground or higher (for a half wave antenna -- the height must be greater if the antenna is longer), you can assume that the ground is perfect and get a pretty good result. Below that height, the calculation again becomes much more complicated because the quality of the ground becomes a factor. If you're interested in the numerical methods used, locate the NEC-2 manual (available on the web), which describes it.

If you're satisfied with approximate results, the work by S.I. Shelkunoff provides formulas for free-space input impedance of antennas with finite diameter wire which can be solved with a programmable calculator or computer. They're detailed in "Theory of Antennas of Arbitrary Size and Shape", in Sept. 1941 Proceedings of the I.R.E. The formulas for R and X contain many terms involving sine and cosine integrals, which can be approximated with numerical series. You'll find additional information in his book _Advanced Antenna Theory_. For approximate calculations of mutual impedance of thin linear antennas, see "Coupled Antennas" by C.T. Tai, in April 1948 Proceedings of the I.R.E. Those also involve multiple terms of sine and cosine integrals.

Before numerical calculations became possible, many very good mathematicians and engineers devised a number of approximation methods of varying complexity and accuracy. You'll find their works in various journals primarily in the 1940s - 1960s.

The complexity and difficulty of the problem is why virtually all antenna calculations are done today with computers, using numerical methods such as the moment method.

In summary, here are your choices:

1. You can calculate the approximate radiation resistance but not reactance of a thin, free-space antenna by assuming a sinusoidal current distribution and using the method Reg described. To include the effect of ground, you have to calculate or look up from a table the mutual impedance between the antenna and its "image", and modify the feedpoint impedance accordingly by applying the mesh equations for two coupled antennas. This method of including the effect of ground becomes inaccurate below around 0.2 wavelength, if the antenna is over typical earth.

2. You can use various approximation methods to calculate reactance, and resistance with better accuracy. But for the effect of ground, you're still limited to being greater than about 0.2 wavelength high.

3. To accurately include the effect of real ground with low antennas, and/or to get resistance and reactance values with arbitrarily good accuracy requires numerical methods. A computer program is the only practical way to do this. A very good basic description of the moment method can be found in the second and later editions of Kraus' _Antennas_.

[*] Cin(x) = ln(gamma * x) - Ci(x), where gamma = Euler's constant, 0.577. . . Ci(x) = the integral from -infinity to x of [cos(v)/v dv] = ln(gamma * x) - (x^2)/(2!2) + (x^4)/(4!4) - (x^6)/(6!6). . .

It sounds like you're using a MININEC-type ground, which isn't
appropriate for this application. Be sure to read the manual sections
involving ground modeling.

One of the tricks I learnt early on with RTV sealant in medical ultrasound water tanks is if you wet the surfaces with water and a detergent wetting agent the sealant wont actually adhere to the prewetted surface. Kind of handy if you wanted to force the sealant into a clearance slot and remove it later.

Or was it oil? Damn I cant remember! I know kerosene is used to pre the surface for better adhesion...

How about paper/masking tape over the gaps and spraying with that gluggy sealant you use on sink drains?

Probably not very useful thoughts, sorry!

Cheers Bob W5/VK2YQA

Bill Turner wrote:
"Without more information, this comparison is flawed."

I agree the information was incomplete. I dfid not reproduce the whole article. The fault was mine, not Phil`s. A low dipole has a high radiation angle. For comparison, Phil was working Airstream net stations in New York, New Jersey, Maryland, Pennsylvania, Ohio, and New England. Phil was located in Ontario near Buffalo, New York when he collected his data. His in-laws lived there. Phil`s home QTH at the time was the highest spot in Western Connecticut, with a line-of-sight path to New York City. Phil had surrounded his mountain top with rhombic antennas pointed toward his likely targets. Amateurs answered when he called.

In the Airstream net, most of the contacts were made Sundays on 3963 kHz at 8 am local time. Sky wave was mostly near vertical incidence. The low dipole was good for the job. Not too directional and a lot of radiation nearly straight up. Phil noted that several times when he switched to to the mobile whip, he could not be heard through the QRM.

The numbers Phil put in Table 3 are only true under the conditions prevailing when he made the checks.

Best regards, Richard Harrison, KB5WZI

Don't know about that, but there's no way to keep the rotor vertical
when lowering a foldover tower... In any case, it's been folded over
(for long periods) many times, and I've never noticed a bearing problem.

>73, Bill W6WRT

Correct on radiation angle, however the average mobile whip at 3.8mhz
is around 10% efficient. Even at 7Mhz it doesn't improve much
efficientcy wise. The low dipole (low being less than .25WL) is
close or better than 95% efficient but has a rotten radiation angle
for DX however close in it will be very good.

Myself in that situation.. I'd put a poles at either end of the
trailer (thats 50ft length) and if possible get it up 30ft or better
and hang a dipole. If the antenna is 66' (40m) the excess length
can hang. The support poles can be anything that will stay up. At
20m 30ft is 1/2WL up and will be decent. Even if you can't do two
support poles and only one make that one high as possible and mount
a dipole as a sloper. It will be somewhat directional but performace
will be far better than any ground mounted vertical that has no ground
plane.

If money wasn't a limiting factor. put down a base and put up a
freestanding tower.

The rules remain. More metal, higher the better.

Same thing as a power flow vector. The dimensions are
energy per second per unit area. If the power flow vector
is integrated over the entire surface of a sphere of radius
r, the result is total radiated power. I thought maybe you
and Mr. Poynting might have worked together at some time in
the 20th century. :-)

==========

Hints and tips -

By the same arithmetical reasoning -

The centre feedpoint input resistance of a 1/2-wave dipole is 73 ohms
plus HALF of the conductor end-to-end HF resistance, which to be
precise sometimes matters. This is exact insofar as 73 is exact - not
an approximation.

The HF resistance of a copper wire at 20 degrees C is -

Rhf = Sqrt(F) / 12 / d ohms per metre,

Where F is the frequency in MHz and d is the wire diameter in
millimetres.

For example, the end-to-end loss resistance of a 1/2-wave dipole at
1.9 MHz using 16-gauge copper wire is 7.07 ohms, which increases the
feedpoint resistance to 73 + 3.53 = 76.53 ohms, to give a radiating
efficiency of 95.4 percent. Some people would consider that's enough
to lose a contest!

Why not start a little notebook to record useful, simple, little
formulae such as above which don't appear in Terman et al? Or if they
do appear then you can never find the right page in the right volume.

Reg.

An antenna doesn't have a single "radiation angle". It radiates at all angles. The relevant question is how much does it radiate at the particular angle of interest, not at which angle does it radiate the most. An antenna which radiates its maximum at a high angle might well radiate more at a low angle than an antenna with a lower angle of maximum radiation.

After almost 50 years banging around Ham Radio I finely have my tower up.. I have each leg of the tower grounded with 2 inch copper strapping , each to their own ground rod.Those ground rods are all connected together and run off to another ground rod I will use that as a common ground. All the coax that come into the house goes to a outside 5x5 box that has poliphaseres installed in it. The box is brass lined and the brass is lapped to another 2 inch copper strap that goes to the common ground. The station ground is separate until it gets to the common ground.. With all this said,I have a questions..
- I 'should' have the power entrance ground run over to the common ground. But it's over 90 feet away and the house has plastic water pipes.. Does it make sense to run a copper wire or strap that far? If so, should it be berried all the way or run exposed. It seems to me the impedance would be so high in the run, that it would be a waste of copper?

Money and space are actually limiting factors, but at least CC&R's arent! My wife and I have been discussing this, and she really doesn't like the idea of something 30 to 40 feet high on a small lot.

Her interest actually is gardening and we had been discussing containing an area of decent topsoil within a square formed by railroad ties. She has no objection to 20 to 25 foot high metal poles on the corners of a square 20 to 25 foot on the side... which turns out to be the core geometry of a 20 meter 4-square broadside phase array.

I would lay the poles first in concrete reinforced holes, connect the feed network and radials on the dirt, and lay feed line underground from the array to just near the trailer. Then I would lay the railroad ties along the square, and then fill the square with topsoil.

Additional radials would need to be buried under a couple inches of red clay fanning out from the square.

Variations:
1) could I create trap verticals from the poles for 20, 17, 15, and 10 meters, or do I need inscribed squares of seperate verticals because seperate phased feeds might be needed for these other bands?
2) could I simply operate the square outside of 20 meters with a tuner for local operation?

I think because space, money, and aesthetics are limiting factors, I need to use precision to my advantage rather than size or height, and a 4 square may help there.

Comments?

Roy,

Thanks, I did and I have tried all the combinations.

I would suspect that 'free space' would show a mis match for 'short radials'. It does not. Simulations of free space dipoles seem accurate. Am I missing something?

I also tried to simulate several values of real earth. None of them produced high input impedance values. What ground values represent suburban clay?

Thanks again,
Dan

> I 'should' have the power entrance ground run over to the common ground.

Hi Joe,

Yes, you 'should,' but only if you find life worth living.

>But it's over 90 feet away and the house has plastic water pipes.. Does it
>make sense to run a copper wire or strap that far?

The 'should' of you 'should' is a requirement of code that is in place
to save your life. It is not there because it has to make sense as an
RF ground lead.

>If so, should it be
>berried all the way or run exposed. It seems to me the impedance would be so
>high in the run, that it would be a waste of copper?

Buried wire will provide an excellent safety ground, but it cannot be
the only safety ground (again code dominates the implementation). And
again, impedance is immaterial to the discussion. If you want an
excellent RF ground, you lay radials, but you connect that ground to
the safety ground for other reasons.

One reason is a mighty big charge called lightning.

Another reason is ground differentials (which occur naturally with
sometimes lethal differences for normal weather, and in great
potential differences with lightning).

If you had two regions separately grounded, and their only
interconnect was a length of coax cable between them, the common being
on the shield, AND if there were a potential difference between the
sites (or a considerable current shunt presented by the coax); then
the first time you pulled the connection on that link you might get
electrocuted. If you want to be a system fuse, what you be rated for?

Not by a long shot. I'm way too poor a student to ever be considered for
a job as a teacher.

> You may want to write a book titled "Story of the 73 Ohms".

It's already been written, by many people who know a great deal more than I.

You'll need to send me the model description (.EZ file) so I can see what you've got. Attach it to an email to me.

> suburban clay?

We have clay here, and by comparing a dipole and vertical at various times of year, I've estimated that the soil is about equivalent to EZNEC's "poor" quality ground in the summer when it's bone dry and "very good" ground in the winter when soaking wet. It's an approximation at best, though.

The free demo version of EZNEC (http://eznec.com) will tell you. Choose a low frequency where the loop is electrically very small. Put a source anywhere in the loop and look at the Source Data. It'll give you the reactance which you can convert to inductance at the frequency you chose. The inductance should stay fairly constant with frequency as long as the frequency is low enough that the loop circumference is a very small part of a wavelength.

"Relative permeability" is the permeability relative to that of free space. The relative permeability of any non-magnetic material, including air, is 1.

>

>
> Note: ï¿½0 = 4ï¿½ï¿½10-7 [Hm-1] (Absolute Permeability)

The permeability of free space (ï¿½0) is 4 * pi * 10^-7 webers/amp-m (MKSA units). The permeability (ï¿½) of anything is its relative permeability (ï¿½r) times ï¿½0.

For your "passing-out" test, calculate the radiation pattern of a two-radial groundplane antenna directly from Maxwell's equations (including the two small cross-polarized lobes that nobody else mentions), using pencil and paper only, in a pub.

I've seen it done by a math professor from W6. (Nah... it must have been a party trick... he must have rehearsed that a million times... mustn't he?)

When he'd finished, Charlie sat back, smiled asked for comments. The rest of us passed out.

I got it!!!!!! Did a google search and was able to figure out the
meaning.

Turns out the inductance of a square, rectange of triangle is almost
teh same as long as the circumfernce, and wire diameter are constant.

Very interesting.

For 12 meters of .01 meter diameter wire, the inductance ranges from
13.7 to 14.0 uh regardless of the shape.

Thanks so much. It's just what I needed, the calculator is handy, I've
bookmarked it.

Regards,

T

Roy, if he reads the impedance value he can determine resonance by the absence of the reactive term.

Do you agree that the SWR scan is a poor method of determining resonance?

Hello Roy,

I do understand that. I also understand when you say radiation angle
your talking about the primary or dominent lobe(s). There may be
many other lobes at useful or less than useful angles present as well.

However, how does that relate to using a shortend antenna with maybe
10% radiation efficientcy to a dipole at a reasonably attainable
height?

An open stub J-pole is the same as a Zepp. 1/2WL element
end fed by 1/4WL balanced series section. The coax connects
to the end of the series section. Arrow Antenna makes one
for 2m. Plans are available that could possibly be scaled
to 915 MHz.

"Harry" wrote about Roy Lewallen:
> You may want to write a book titled "Story of the 73 Ohms".

It should include the point that the 73 ohm radiation resistance value applies to a physical 1/2-wave, thin-wire, linear dipole in free space, and that a reactance term of + j42.5 ohms also applies to such a configuration (Kraus 3rd Edition, p. 182).

The dipole length needs to be shorted by a few percent in order to zero out the reactance term, at which time the resistance term will be about 65 ohms.

~~~~~~

That's true, except few if any hams have a specific "angle of interest", since different angles are used at different times. For most of us, the angle of maximum radiation gives a general indication of how the antenna will perform. A better indication would be a graphical representation. It's always a problem when one tries to reduce a complex situation like this down to a single number.

Any reason you're not considering a 20 meter dipole, fed with
ladderline to a tuner, for 20 thru 10 meters? Put it 25 feet high, and
it's nearly or more than a half wave high on all bands.

Hi, Paul -

If you have the 2004 ARRL Handbook, the antenna is described on page 20.17
as a resonant feed-line dipole. The figure on that page shows its construction.

If you do not have the handbook, I can scan the page and send it to you.

However, how does that relate to using a shortend antenna with maybe
10% radiation efficientcy to a dipole at a reasonably attainable
height?

Well....Exactly as he described.
> An antenna which radiates its maximum at a high angle might well
>radiate more at a low angle than an antenna with a lower angle of
>maximum radiation.

The thing is "might".... My mobile antenna on 40m is *much* less
efficient than my dipole at 40 ft. But...It still is the best to longer
hauls over about 800 miles, and to dx. In it's case, it does radiate
more at the lower angles I'm using at that time, vs the dipole.
With some lesser mobiles, "mine is fairly stout", this might not be
the case. The best antenna should always be decided to fit the
usual paths to be used. In the case of my mobile vs the dipole, it's
possible that if the dipole were raised another 1/4 wave higher, it
could match the mobile at those lower angles.
At home, I often ran a dipole at 40 ft vs a full size ground plane at
the same height. Both were pretty efficient. Efficiency comparisons
were fairly useless as to actual performance. What really decides
which is best at a given time, is the path, and angles to be used.
Now, if you compare two same length low dipoles, both to NVIS, both
shooting straight up, and one is less lossy than the other as far as
feeding method, etc, then yes, efficiency will decide which one is
best.

I am actually quite peaceable and believe in living and letting live in most
cases. Who I allow in my home is up to me and whom I refuse entry is not
the purvey of HOA Nazis. And, again, it is why I chose an older home
(1956) with plenty of room, almost ZERO crime, and NO
HOA's. Now should I run into one of those SOB's that start telling me what I
can or can't do, then it will become another story. I feel so strongly
about property rights that I would go to WAR over it, both nationally...or
on a personal basis. Like, I wouldn't be averse to whuppin' some
smartmouth's you-know-what over it. Again, being very quiet and peaceable as
I certainly am, I am also quite intimidating in stature, so it would be an
interesting fight! LOL! Now, it *could* even get down to the point of
"You SOB, you can tell me what to do when you get around on the backside of
my shotgun, or you got enough
a$$ on ya to MAKE me, you *&^%$#"! LMAO!

In Charlotte, NC, this year, there was a case where the HOA Nazis and their
powermongers went too far with "foreclosures" and the NC legislature put
some restrictions on their ability to foreclose with respect to their
"rules".

Now, foreclosing on someone's house because some Nazi b#####d didn't LIKE the peoples' guests? NOT!
(Not me because I don't HAVE that problem) I can see how this could cause somebody to get severely injured or KILLED! You don't MESS with one's home! :(I feel for those who have to put up with such nonsense! OTH, one should NEVER move into such a place, either, so he bears some of the blame. :)

Best to all,

Jerry

560. Re: best HF antenna system next to a trailer?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-14 17:43:41 UTC

Source record: 70657

I think because space, money, and aesthetics are limiting factors, I
need to use precision to my advantage rather than size or height, and a
4 square may help there.

Sounds like too much work for my lazy a$$... :/ If you did that for
20m, it's kinda stuck , as far as spacing, etc, for good performance
on the other bands. Me, on 20m...I'd be using my mobile antenna.
And I'd probably be hanging pretty close with any "fancy" antenna.
When I'm mobile, 20m up, there is *no* disadvantage vs being at
the house on dipoles, etc.. At least as far as talking. On 20m, my
mobile is LOUD. I can work dx at the drop of a hat, and still do
well stateside. Even on 40m, there is little real disadvantage to
being mobile vs the dipole at home. Even in the daytime. Say if
I'm 20-30 over 9 at home, and drop to 10-15 over 9 in the mobile.
Doesn't
amount to a hill of beans... Same for 75m. But in the summer on 75m,
I do recommend a dipole/loop, as it will be worth quite a bit in
getting
over the noise running NVIS. I could talk with the mobile just fine,
but the dipole will make me "full quieting" to use an expression...
It's like throwing on an extra 500w when you are shooting upwards...
I wouldn't underestimate how well a *good* mobile antenna could
work on the higher bands. If it's mounted up high on a trailer, etc,
it should work well. It's like being on a huge car. The only problem
is
changing bands...You need to be able to reach it to change taps,
etc.. But that can be easy with a quick disconnect. That's what I
use on mine. I can't reach my coil when the antenna is on the trucks.
With the disconnect, a twist, and it's off. Also good for theft
prevention..
A good screwdriver could be an option too.
Not saying you can't try other antennas, but just saying , a good
mobile
will get the job done, all by itself. And it's pretty simple and easy
to
look at visually. It will often outplay ground mounted trap verticals
with mediocre radial systems on the higher bands.

No, I usually use the SWR sweep to determine resonance. Stepping the cursor and looking at the impedance at each step quickly identifies the resonant frequency to within the closest step. Additional narrower scans are done as necessary to get more precision. What method do you use that's better?

Better yet, you can superimpose the plots from two antennas for direct comparison. In v. 4.0, you can even get a numerical readout of the difference between the two in dB at the angle of the cursor (the little green ball).

The context was that one antenna was better for DX than the other
because it had a "lower radiation angle". An antenna with a "low
radiation angle" which is 10% efficient probably radiates less at low
angles than a more efficient antenna with a "high radiation angle".
Therefore it's not a better DX antenna. My point is simply that the
angle of maximum radiation is not a valid criterion for comparing antennas.

I agree, which is why EZNEC produces a graphical output. I encourage people to look at it rather than reducing the pattern to a single number. And I have to emphasize once again that what really counts is the field strength, not the pattern shape. An antenna can have a wonderful looking pattern with nearly all its radiation at low angles, and still be a poor antenna for DX. Or with nearly all its radiation at high angles and be a poor antenna for short range communications. One familiar example is a Beverage antenna, which has a lovely pattern shape but makes a poor transmitting antenna. A quarter wave vertical will nearly always do much better for transmitting, even at the angles favored by the Beverage.

Very interesting references. In particular Kraus' 2nd ed. pp 359 - 408.
Also Stutzman and Thiele, 1st ed. pp 306 - 374. Pretty much grad level,
needs effort, (for me) even though I took Stutzman and Thiele's antenna
course in 1998 (NCEE).

Regards,

Frank

Just a quick question.
What is the impedance at the centre of an infinitely long dipole (in
free space)?
Ian.

Hi Cecil,

I find another formula in Balnais book (section 4.3, 1982 edition)
for Rr:

Rr = 20 * (pi)^2 * (l / lamda)^2 (4-37)

If l = lamda/2, then this formula gives Rr .=. 50 Ohms.

(4-93) the one you quoted is

Rr = (120*pi) / (4*pi) * Cin(2*pi) = 73 Ohms, (for l = lamda/2)

where 120*pi is the intrinsic impedance for a free-space medium.

Would you please explain the difference between these
two formulas (4-37 and 4-93)?

Thanks!

4-37 should apparently read:

Rr = 30 * (pi)^2 * (1 / lambda)^2.

Equation 4-37 is from section "4.3 SMALL DIPOLE", i.e. shorter
than 1/2WL. The dipole is so short that its current distribution
is triangular, not sinusoidal. Quoting section 4.3: "The radiation
resistance of the antenna is strongly dependent upon the current
distribution." The "1/2" on the diagram does NOT mean 1/2WL.

Equation 4-93 is from section "4.6 HALF-WAVELENGTH DIPOLE". The
current distribution on the thin-wire 1/2WL dipole is considered
to be sinusoidal.

See Figure 4.8. Note the triangular current distribution for
L = 1/4WL and the sinusoidal current distribution for L = 1/2WL.

Thanks for the feedback everyone.

The article Jerry pointed me to starts looking like the commercial antenna I was initially studying. Their unit though only had a 1/4 wave above the coaxial sleeve.

From the SMA plug, the coax coiled around the radome must have been the choke to help reduce RF currents radiating from the earth braid.
Then the 1/4 wave length coax forms the match followed by the expose radiating section.

It looks like an open stub fed J-pole where the stub is enclosing the inner element rather than being constructed as a rod next to it.

Does this seem reasonable ? (PS. I'm a beginner with regards to antenna theory and would like to understand what is happening so that I can experiment with some kind degree of success).

> The Eternal Squire

How about the screwdriver antenna. This is compact, can even be "disguised" inside a PVC pipe, can be positioned vertically OR horizontally and can be used to tune a random wire strung into a nearby tree. I used this system on a motor home where we positioned the antenna on the rear ladder with a swivel mount. When traveling, the antenna was positioned at a 45 degree angle and rested in a wooden cradle on top of the bus. At rest, the antenna could be raised to the vertical in a minute or two and tightened with thumbscrews. Because the motor home was mostly fiberglass, we quickly discovered that the antenna could be used in the semi-horizontal position while going down the road with good results! In your case, your trailer would be a "mobile", but you could set it up in several ways to take advantage of various situations, and, also tune a random wire with it. I've done this while on field exercizes with CAP.

Now I know I am partial since I make screwdrivers, but you can find a variety of makers on the web. Just try to avoid the ones made of PVC and, of course, there are those that are SUPER expensive. Go for the ones with larger diameter coils and wire sizes and avoid the ones that promise 160 thru 10. Those that promise 160 thru 10 are the ones that are wound on small diameter forms and are wound with 20 gauge wire CLOSELY together (in effect, transformer-wound) which destroys your "Q".
I doubt seriously such an antenna would do much "punkin" on 160!

Every body runs into compromises at times, so you have to be do the best you can do with what you have to work with.

If you have 75 feet of room over your lot, then you might visit www.k1jek.com for an all-band dipole 80-10 Meters. I'm told this is a good choice for short lots.

Hope this helps

Yes, it does. Take a look at the following:

http://download.antennex.com/hws/ws1002/sperrtof.pdf

A Sperrtof, in effect, is a J-pole whose matching section is a coaxial tube rather than a single rod or wire. It sounds rather like what you're describing.

As with all such (I think), the radiating section is 1/2 wavelength long, give or take a smidge, and behaves as an end-fed 1/2-wave dipole. The matching section isn't supposed to radiate significantly.

The overall radiation pattern would, I expect, be essentially the same as other J-poles and other end-fed 1/2-wave radiators - similar to a center-fed 1/2-wave dipole, but tilted a bit "upwards" away from the feedpoint.

You can distinguish a Sperrtof-type antenna from one of the coaxial dipoles Jerry referred you to, by the length of the single-wire radiator - it's 1/2-wave for a Sperrtof and 1/4-wave for a coaxial dipole (which is really a center-fed dipole).

There's an interesting dual-band 2m/440 antenna which was written up in QST in October 2000 - ARRL members can get the article at http://www.arrl.org/members-only/tis/info/pdf/0010050.pdf

It's interesting because it's _called_ a J-pole, _looks_ like a J-pole... but electrically it isn't. It's actually a center-fed

vertical, not a Zepp. The stub at the bottom acts as a
choke/decoupler, not as an impedance transformer.

582. Re: Open Stub fed J antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-15 01:41:06 UTC
From: David <groups@orbitcoms.com>
Message-ID: <Si4We.47593$FA3.15680@news-server.bigpond.net.au>
Source record: 70579

Dave,

If I scale that up to 915MHz, the dimensions are almost perfect for using RG58 coax instead of the copper tubing.The outer tube would be 5.5mm and inner conductor 1.6mm. Being 50 Ohm coax, I assume therefore I do not need to slide the tap point up as their design did. I suppose I should also add the choke coil at the antenna base for additional isolation of ground currents.

The article mentions the top part as 1/2 wave and bottom at 1/4 wave. If the bottom part of their design is 505mm then the antenna must be used for 2m band. If this is the case, how come the radiating element is 1480 long ?

The Coaxial antenna mentioned in the article mentioned by Jerry looks good. The version they mention with a GAP would be simple to construct. It is a 1/4 wave radiating element at the top (earth braid stripped back), then 1/4 wave of full coax, then a "small" gap, then the transmission line. They do not mention the size of the gap but I assume any small gap has the same effect of isolating the reverse current ?

Should the actual lengths of these sections be modified by "K" depending on diameter of conductor or are they exact 1/4 wave length cuts ?

Thanks heaps.

Very good,..... thanks a lot!
Your figure 4.8 (second edition) is figure 4.7 in the first edition.
These current distribution curves (1/4, 1/2, 1, 3/2, and 2 Lamda
length)
are interesting to study.

I wouldn't use RG58 for anything above HF. It has 20 dB
matched line loss per 100 ft at that frequency.

Source record: 70582

So for the 1/4 wave (81mm) section of the antenna the loss would be
about 0.05dB ? at 915 MHz.

I typically have between 150mm (When antenna mounted on enclosure) and
2m length (when antenna external to enclosure) cable between transmitter
and Antenna. (Around 1.2dB max. loss in coax between transmitter and
antenna). Would this usually be acceptable or do you aim for much lower
loss in the transmission line ? Max. power is 1 Watt. Most of the
transceivers I play around with are around 10mW.

Thanks

Depends upon whether you leave the insulation on the radiating
part or not. But what I was concerned about is the transmission
line. You lose about half of your power every 15 feet. Until
your last posting, you didn't tell us the length of the
transmission line but personally I find 1.2 dB matched line
loss in six feet to be unacceptable. Any SWR above 1:1 and the
losses are even greater.

While I would agree with officious and petty, moron and bigot do not apply
from my readings.

I get really tired of that old saw being hauled out and applied to people;
simply because others disagree with their actions.

A few moments spent perusing a dictionary will show that simply refusing to
take in a storm victim, while abhorrent to me, does not make one a bigot.

594. Wooden I section pole

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-15 16:36:27 UTC
From: John N9JG <john@gotwals.xremovey.com>
Message-ID: <dgc7u7$9h8$1@mailhub227.itcs.purdue.edu>
Source record: 70591

I am in the planning stage for a 160 meters compact loop antenna. A loop antenna may not have metal nearby, so I am planning to use a wooden pole to support the top of the loop. In the ARRL Antenna handbook, it states that "W5QJR made a pole of 2 x 4-inch lumber with 1 x 4-inch boards on either side to form an I section. He held the boards together with 1/4-inch bolts, 2 feet apart and tied rope guys to the top. This made an excellent mast up to 50 feet high."

Does anyone have any comments on the feasibility of an unguyed pole using this same type of construction? Naturally, a portion of the pole would have to be underground, and perhaps set in concrete. What about a 50 feet pole, with 10 feet underground ,which would give you a 40 foot mast?

An alternative would be to have a contractor install a 40 feet utility pole, but I assume the wooden pole described above would be less of an eyesore (to the neighbors) than a utility pole.

Any comments and advice will be appreciated.
John, N9JG

Even more frustrating is the number of school buses controlled by a black Mayor that never were put in to evacuation service. The same buses now set in water and I am sure they will be replaced at taxpayers expense.

As I was somewhat involved in the political debacle, I can tell you from personal experience that Red Cross and amateur radio vans were prohibited from entering the disaster area.

My cynical side says that in the background, a chance was both seen and taken to make George Bush look bad. The democrat political machine in New Orleans is only surpassed by that of Chicago.

I know for a fact the Red Cross was told that if they were to feed the people in the superdome they would stay.

Some how I find it ironical that a black mayor applied the same wisdom to his people that my mother applied to the neighborhood stay dog I attempted to feed.

Where were all the murdered bodies, in the superdome, the press reported on so breathlessly?

The must have hid them in Al Capone's vault to make Geraldo look bad; as he worked for the evil Fox network...

Of course the more the race card is played, the more money is offered by white America to assuage the implied guilt. Black poloticos have learned this lesson well!

If the poor people of New Orleans didn't have transportation out of town
it was because their elected Mayor refused to have them humiliated by
having to leave town in a school bus or city bus. He wanted Greyhound
busses with working air-conditioning for them.

It's in the disaster plan to use busses for evacuation. Read it.

Hi Walt,

Being bigoted does not necessarily mean one is racist. Bigots can
focus their intolerance on many subjects and be perfectly race-free.
On the flip side being racist automatically carries the label bigot.

Bigots are quite easily recognized, that is why there is the name to
denote the obvious. Certainly there is nothing subtle about this. I
cannot say that I have seen more than 20 minutes coverage on the
storm, especially when "news" is so evidently not informative as it is
salacious entertainment. They could have as easily run the movie
"Twister" to no different effect.

Further, those 20 minutes were not watched here, but in England where
the world was astonished by the third world class of impoverished
action taken.

As such, the folks at Fox would call me a bigot for being intolerant
of their coverage. However, it would be the Fox folks who serve the
American feed because their International feed was distinctly
different. None of you probably observed Rumsfield's visit,
un-edited, where the populace in a rage were yelling "Fuck YOU" at
him. I would suppose they were bigots too, given the inflexibility of
their opinion after rafting on the rooftops.

Fox was content to satisfy any audience, and I suppose that makes them
most catholic. [For those who are short on dictionary skills,
catholic means liberal or tolerant, a most amusing irony applied to
the Fox organization that literally serves all masters.]

A vertical conductor, a metal tube, running diametrically across a large magloop with the tuning capacitor at the top, has no effect either on radiating efficiency or the radiation pattern. It may as well not be there apart from providing a prop or support for the antenna itself. It will, of course, need to be well-insulated from the high-voltage parts.

In general, provided the longest dimension of foreign metalwork is much less than 1/2-wavelength, and there is not much of it, negligible loss will be induced in it. This is due to the very low loss resistance of most metals.

Metalwork in the vicinity of beam antennas may upset only the radiation pattern.

Short lengths of foreign metalwork in close vicinity of tramsmission lines, such as open-wire and ladder lines, will cause neglible loss but will slightly reduce the line impedance Zo which might affect the L and C settings of the tuner.

But beware of "semi-conductors", like damp wood such as foliage and tree trunks, in the near-fields of antennas and lines. Their higher impedance provide a better power match to the 'generator'.

You can have as much foreign polyethylene as you like.

Reg.

I'm deciding to go with a 20 meter 4-square because it can hopefully provide me with similar directivity and DX takeoff angle as a 20 meter beam but without the hassle or height of a tower. A dipole only has directivity in 2 directions, a 4 square can give me directivity in 4 directions with basic phasing and 8 directions high tech using ARRL suggestions. The EZNEC plot was pretty awesome.

>using RG58 coax instead of the copper tubing.The outer tube would be
>5.5mm and inner conductor 1.6mm. Being 50 Ohm coax, I assume therefore I
>do not need to slide the tap point up as their design did.

Bad assumption, I think. The portion of the matching section between
the tap point and the bottom is a shorted stub, which adds some
inductive reactance at the feedpoint. If you don't have it, you won't
get a good match.

Another approach I've seen to creating the necessary shorted stub is
to just use RG-58 and a simple BNC "T" connector. If you look at the
Sperrtopf antenna design, picture it made this way:

- one long piece of RG-58 1380 mm long, with the upper part of
the outer shield removed... that's your radiator, and the portion
of the matching section above the feedpoint.

- A second section of RG-58, about 100 mm long, with one end shorted.
That's the stub.

- The feedline RG-58.

Now, just connect all three together... radiator/matching section,
stub, and feedline. You can solder 'em, or add BNC plugs and use a
BNC "T". If you do the latter, remember to include the lengths of the
plugs and "T" into account.

> I suppose I
>should also add the choke coil at the antenna base for additional
>isolation of ground currents.

Certainly would not hurt to do so. You could either coil the coax
below the bottom of the matching section, or add a quarter-wave choke
sleeve, or just run the coax through a few ferrite beads.

>The article mentions the top part as 1/2 wave and bottom at 1/4 wave. If
>the bottom part of their design is 505mm then the antenna must be used
>for 2m band. If this is the case, how come the radiating element is 1480
>long ?

I think there's some confusion in the antenna schematic diagram,
compared with the text and parts list. The diagram appears to show

the upper (radiating) portion of the center element being 1480 mm, but the parts list indicates that the *total* length of the inner element is 1480 mm.

The latter seems more correct to me... it'd give you a radiating element of (1480 - 505) = 975 mm, which is a bit less than 1/2 physical wavelength at 2 meters. This seems reasonable to me given that the radiating element is fairly thick (10mm) rather than a thin wire.

>The Coaxial antenna mentioned in the article mentioned by Jerry looks
>good. The version they mention with a GAP would be simple to construct.
>It is a 1/4 wave radiating element at the top (earth braid stripped
>back), then 1/4 wave of full coax, then a "small" gap, then the
>transmission line. They do not mention the size of the gap but I assume
>any small gap has the same effect of isolating the reverse current ?

I'm not clear about the gap configuration either. The article sort of implies that its size has to be set experimentally, so that the leakage current through the gap is the right amount to cancel out the signal propagating back down the outside of the upper section. The article doesn't say whether the gap is supposed to go around the full circumference of the coax (completely isolating the upper and lower portions of the shield) or only partially around... I infer that it's the latter, because I don't see how the antenna could work with the shield sections fully separated.

>Should the actual lengths of these sections be modified by "K" depending
>on diameter of conductor or are they exact 1/4 wave length cuts ?

Well, I think it's a bit of a compromise.

The upper section (the coax center conductor and its surrounding dielectric) is going to have a velocity factor of not much less than 1.0. Cutting to 1/4 physical wavelength, and then trimming a bit, seems likely to work.

I think the lower section is likely to be a bit trickier, since there are actually two velocity factors involved. The radiating is done by the RF travelling back down the outside of the coax braid from the feedpoint, and this (like the upper section) will have a velocity factor close to 1.0, which suggests that the gap-to-feedpoint distance should be close to 1/4 physical wavelength.

HOWEVER: the signal travelling up the *inside* of the braid, like that travelling up the inner conductor towards the feedpoint, will be travelling more slowly - the velocity factor will be somewhere around .66 - .8 depending on cable type. This means that there will be more than 180 degrees of phase delay between the signal passing the gap going upwards (inside the cable) and the signal reaching the gap from above (travelling back down the outside of the cable). Hence, the gap leakage won't result in full cancellation of the signal travelling down the outside of the coax past the gap.

To get the two signals into accurate 180-degree phase opposition,
you'd need to make the distance from the feedpoint to the gap a bit
less than 1/4 physical wavelength, but a bit more than 1/4 of the
coax's usual electrical wavelength. Splitting the difference might
work fairly well.

I'm not sure what this will do to the antenna's feedpoint impedance /
return loss, though, and it'll probably tilt the antenna's radiation
pattern somewhat. You will probably need to experiment to get the
best compromise between antenna pattern and feedpoint impedance /
return loss / SWR. The same is true of the gap size and configuration.

Roy,

I decided to go with a 20-meter 4 square. I wonder if any people have experience with 4-squares that they can share with me. I have considered some construction details give available materials, and I have some questions.

1) Can I shorten each element by using an inverted L rather than straight vertical, with a pipe as vertical part and a wire as horizontal part? I have heard that matching is far less of a problem this way also.

2) Where can I find or build a reasonably inexpensive phase box?

3) For the vertical part, I am wanting to a dig a hole 2 foot across by 3 foot down, and fill with concrete. Into this I would insert a 5 foot length of 1 1/2 inch steel support pipe about midway, so that 2 1/2 feet are above ground. Into this I would mount a 10 foot length of 3/4 inch steel pipe with a 2 1/2 foot insulated overlap of PVC pipe. The 3/4 inch steel pipe would be the bottom of the actual driven element. Into this I would mount a 10 foot length of 1/2 inch aluminum pipe with a 2 foot metallic contact overlap, and then I would finish with rod for vertical or wire for inverted L.

Question: how would the 2 1/2 foot overlap of a non-grounded metal support pipe interfere with radiation of the vertical element?

Thanks in advance,

The Eternal Squire

The small "eye of the needle" gate at the walls of a city
was sized for human beings. It was camels that couldn't
get through it. Camels had to enter through the main gate.

True. You can alter the lengths and use the stub section to cancel
the inductive or capacitive reactance set up by the radiating element
if present. If your radiating element is capacitive (tad shorter)
then the stub can be open which will reflect as inductive. It's only
a matter of juggling the numbers.

For 2m the correct length for the total center element is 1480 (58").
At 2m the halfwave length is in free space is 1M or for real elements
about 38" (.95M) or a K around .96-97.

>The latter seems more correct to me... it'd give you a radiating

Correct. Thick elements do make a noticeable difference especially
when the ratio of wavelength to element diameter gets below 500:1.
The effect is elements are shorter, bandwidth wider.

>>The Coaxial antenna mentioned in the article mentioned by Jerry looks
>>good. The version they mention with a GAP would be simple to construct.

There is no requirement for the bottom to be coaxial. it can be
parallel lines (convential Jpole) in either case the antenna is a
1/2 lamda using a open section of transmission line for matching.

>I'm not clear about the gap configuration either. The article sort of

The gap is fully open. Also that gap sets up a transmisstion line
between the outer braid and the inner transmission line braid.
There is an interaction between the gap and braid section length.

>>Should the actual lengths of these sections be modified by "K" depending
>>on diameter of conductor or are they exact 1/4 wave length cuts ?

Yes. however the difference between K and free space will be maybe
a 2-4% difference. At 2m that comes out to around .5" (12mm) give or
take.

>Well, I think it's a bit of a compromise.

If properly matched the feedpoint will be 50ohms and the return loss
will be reflective of a good match.

Hi Hans,

I will leave that to other faiths to describe for themselves. One
distinct difference between Christian charity and Islamic charity is
that Muslims are commanded to give the expected portion of their
charity directly to the afflicted. This means hand-to-hand.

>, and do I need to be a
>member of your cult in order to get through the eye of the needle (and why would
>I want to?)?

Complete the allusion and enlighten us to which cult offers fare
discounts for buying the way to Heaven. Of course, if you have no
interest in the destination, then the subject is rather transparent
and hardly requires comment.

Hans, Richard has obviously followed Christian principles by
selling all that he owns, giving the proceeds to the poor,
and becoming a pennyless missionary. But wait, he appears not
to have sold his computer yet. :-)

There's that "takeoff angle" again. Having a good "takeoff angle" is no guarantee of good DX performance, and isn't a valid way to compare the performance of two antennas.

You should model both the beam and the 4-square. Make sure you include a realistic amount of ground loss resistance for whatever ground system you think you can put down for the 4-square. Superimpose their elevation patterns on the same plot, and see which really does best at low angles. If you don't want to go to the trouble of modeling a beam, you can model a simple dipole which has almost the same elevation pattern as a beam of a few elements (in the forward direction) at the same height. Mentally add the beam's gain relative to a dipole to the dipole's pattern. See if the 4-square really is as good. It might change your mind.

I've built and used a few, for 40 meters.

> 1) Can I shorten each element by using an inverted L rather than
> straight vertical, with a pipe as vertical part and a wire as
> horizontal part? I have heard that matching is far less of a problem
> this way also.

You can make a 4 square from any kind of element. EZNEC can tell you what effect the element shape will have. I strongly recommend against designing the antenna to get the best or easiest match. Design the antenna for the best performance, then design whatever matching arrangement you need in order to match it. An exception to this general rule is that antennas with an exceptionally low resistance or high reactance might not be practical because of the problem of matching system loss, so such an antenna might need redesign in order to be practical.
>
> 2) Where can I find or build a reasonably inexpensive phase box?

Chapter 8 of the ARRL Antenna Book describes how to design one. See also "The Simplest Phased Array Feed System - That Works" and accompanying program Simpfeed, available from http://eznec.com/Amateur/Articles/.

Wow, for a 20 meter 4-square? For each element on 40, I drove a 1-1/4" 8 foot galvanized chain link fence line pole 4 feet into the ground. (Our soil is clay.) I cut a piece of heavy wall PVC pipe lengthwise into quarters for insulators, and clamped the element to the line pole with muffler clamps with a couple of pieces of the split PVC pipe in between.

The elements are three pieces of telescoping 6061-T6 tubing, beginning with, as I recall, 1-1/8" at the bottom. They've been up for around 20 years now and survived a couple of pretty strong wind storms.

>
> Question: how would the 2 1/2 foot overlap of a non-grounded metal
> support pipe interfere with radiation of the vertical element?

Any shunt impedance will reduce the null depth if the array is adjusted for the correct base current ratio. This is because a different fraction of the current will be diverted from each element because of their differing base impedances. However, I've found that the 4 foot overlap I have doesn't reduce it noticeably. But my overlapping pipes are parallel and, if I understand your description, yours will be coaxial. That'll result in a lot more shunt capacitance, and a correspondingly greater effect on the null. The main lobe won't be affected much.

Source record: 70622

Thanks everyone for your feedback to my posting.

I have now been given a lot of information but am starting to go around
in circles.
It seems many people are used to operating at lower frequencies with
huge lengths of wire and hundred of watts of power.

In my application, I am looking for an omni-directional antenna with
reasonable "gain" and fairly low radiation angle. The application
operates with Data at 920 MHz where power levels are below 1 watt. The
antenna must either fix directly to the enclosure (which can be plastic
or metal and is usually only around 100mm x 60mm x 40mm) or within 2-3m
of the enclosure. Therefore, a unit that does not require ground plane
style antenna would be good.
The end-fed antenna style is good because I can build it into the end of
a SMA connector and use 1/4" nylon tubing as the Radome.

Now I just need what goes in the Radome to complete the unit. It is
difficult to install Tee BNC connectors and mid tap points on coils or
transmission lines etc. Stripping coax cable and coiling the coax on the
outside of the Radome is fine as I can cover the unit later with heatshrink.

In my search it seemed the J-pole was a good contender due to its
performance and low radiation angle and ground independence. The shorted
stub version was troublesome but the open stub looked promising.

It appeared as though I could simply use coaxial cable to create the
antenna and fold back part of the coax over 1/4 wave section.

Some have suggested coiling cable to act as a choke at the feed point
and others have mentioned not to do this.

Would anyone by chance have details of a whip antenna that is proven to
work and is similar to what I am trying to construct that I could use as
a starting point ?

Thanks in advance.

In "Antennas For All Applications", by Kraus and Marhefka, third edition,
page 824, a 1/2WL over 1/4WL collinear array vertical is described that
allegedly has a gain of 6.4 dBi. There is a 180 deg. phase reversing coil
between the bottom 1/4WL and the top 1/2WL. The entire vertical should be
less than one foot long. The 180 deg. phase reversing coil is the tricky
part.

"friend" I challenge you to quote an official Catholic source to support your 'sale' assertion!!

For those who may be interested in putting this outrageous statement to rest, I suggest a trip to your local library and read the official position of the Catholic Church. It is openly published in the public documents of the Second Vatican Council, in a book titled "VATICAN COUNCIL II - The Councilar and Post Councilar Documents", Section 1 titled: "The Constitution on The Sacred Liturgy", dated 4 December 1963, Sub-section 1-6, dated 1 January 1967, titled "Indulgentiarum Doctrina" paragraphs 1 through 18.

Please note that "an_old_friend" has stated another outrageously erroneous misuse of language. 'friend' states "DOGMA". The official pronouncement is DOCTRINAL, not Dogmatic. There is a very significant distinction between the two words.

It has NEVER been the DOGMA of the Catholic Church to sell indulgences. PERIOD! A period of clerical abuse of indulgences, contrary to the Doctrinal position of the Church, did exist in history. Martin Luther was correct to cite this failure in clergy practice. The abuse was censured in the Council of Trent [ca 1545 - 1563].

Note[1] to 'an_old_friend': be sure of your facts before you post outrageously erroneously statements.

Note[2] to 'an_old_friend': your 'prod' sources are also in error.

Signed Ham Op, Catholic Clergyman

Dear Group:
Long, long experience with angles above the horizon that are used by DX signals (at HF) indicates that the most useful angles are between 2 and 12 degrees. Comparing the expected gain of antennas at 6 degrees provides a good figure-of-merit.

That said, if one has a low, horizontally polarized antenna with very little gain at 6 degrees, you might still work DX using more than an optimum number of hops (angle of more than ten degrees). However, you will work DX fewer days per month than someone who gets significant gain at angles smaller than ten degrees.

I emphasize what Roy has said: the so-called take-off-angle (equal to the smallest angle at which peak gain occurs) of an antenna is not necessarily an indicator of DX performance.

Another example is the case of a horizontally polarized antenna that is over 3 WL high: it has a small TOA but is likely to have a null at an important angle smaller than 12 degrees. In other words: the too-high-antenna works very well some of the time, but a lower antenna works better at other times.

A useful goal for the (single) optimum (for DX) antenna is an antenna that has its second null (first null is at zero degrees) at an angle greater than 12 degrees and a first maximum (what is called by many the TOA) between 2 and 12 degrees.

The actual angle used at the transmitter end of a DX circuit is sometimes quite different from that used at the receiver end.

For UHF, you might prefer to use a 1/4-wave short-circuited stub in place of a coil to reverse the phase. My 19th edition of the ARRL Antenna Book shows such an antenna, "the super J-pole on page 16-25. At other frequencies, this might be called a "Franklin Antenna". It`s a 1/2-wave in-phase with another 1/2-wave, one mounted directly over the other.

The super J-pole is designed for 144 MHz, but can be scaled for any frequency with proper mechanical allowances. Gain is about 6 dB over a 1/4-wave whip.

Best regards, Richard Harrison, KB5WZZI

==========

It's because neither the authors nor the editors were aware of it.

The near-field on the surface of an antenna's conductors starts off at a very high value. The far-field is zero at zero distance.

The near-field fades into the distance just the same as the ar-field - only much faster. It also has a radiation pattern which depends on an antenna's structure.

For argument's sake, for an isotropic antenna (which doesn't exist), at a distance of 1/2/Pi = 1/6 of a wavelength from the antenna, the near-fields and far-fields are equal to each other but differ in phase. They both exist together and their effects on foreign bodies are inseparable from a measurements point of view. They exist seperately at all distances only as a mathematical fiction.

The near-field of open-wire transmission lines is sensibly zero at a distance of 4 or 5 times the wire spacing but the radiation field is finite and very small. The radiation field increases with wire spacing and is a maximum when spacing is about 1/2-wavelength which nobody ever uses. This accounts for the lack of use of low-loss open-wire lines at UHF and higher frequencies.

Back to Magloops where the measurement unit is loop diameter rather than wavelength and the near-field is mainly magnetic. The magnetic field falls off at a rate proportional to the cube of distance. I would be very happy with a distance of 1/2 the loop diameter or more between the loop and large foreign bodies such as the ground.

Highly conductive metallic bodies merely slightly detune the loop with little additional loss.

To Novices -

It is use of the term "take off angle" which causes all the confusion surrounding DX and the "best" take off angles. It is a misnomer.

The elevation angle of a radio path between two stations is purely a geometric function of their locations on the Earth's surface and the heights of ionospheric reflecting layers. It has nothing whatever to do with either of the antennas or ground conditions - except that it is the best elevation angle at which an antenna beam should be pointing.

If, purely by coincidence, the "take off angle" indicated by Eznec happens to be the same as the exceedingly changeable "path elevation angle" then all is well and good.

The true "take off angle" having maximum gain (another misnomer) for any vertical antenna is always zero degrees, ie., it corresponds to the always existent very strong groundwave. Whereas Eznec always reports the groundwave strength as being zero. It is of no use in the prediction of often-used ground waves between stations.

Whenever a resistive ground is involved, programs like Eznec do not produce the true radiation pattern of an antenna. Not that there is anything incorrect with Eznec. It is just the confusing description of what it displays.

Reg Edwards wrote:
> . . . Whereas Eznec always
> reports the groundwave strength as being zero. . .

If you're using the strict definition of "groundwave" as being the field at an elevation angle of zero, only EZNEC's far field analysis reports it as zero, because (as the manual explains, and as I've explained here several times before) the far field results are valid at a distance beyond the point where the surface wave has decayed to essentially zero -- a few miles at HF. And at that distance, the field at zero elevation angle is zero if the ground conductivity is finite. If the surface wave strength is wanted, it can easily be found using EZNEC's near field calculation, which calculates the total field at any point in space -- including just above the ground surface.

It is of no use in the
> prediction of often-used ground waves between stations.

Unless you use the near field results, which do give an accurate indication of the field at any point in space. I assume you've just forgotten the several times I've explained that to you. Maybe this will be the magic time it'll sink in.

> Whenever a resistive ground is involved, programs like Eznec do not
> produce the true radiation pattern of an antenna. . .

For sure, the modeling of ground is the weakest point of all antenna modeling programs including EZNEC. But the pattern is generally a good representation of reality. Remembering, of course, that the far field pattern is just that -- the pattern at a distant point at which the surface wave has decayed to zero.

A graphical pattern which includes the surface wave component would be different at every distance from the antenna up to the distance where the surface wave has decayed to essentially zero (a few miles at HF). The field strength at angles greater than zero would be of little interest to amateurs doing local communication by surface wave. Those who want to know the field strength at ground level at any distance can easily get this information from EZNEC's near field analysis (which reports the total field, not just the near field).

Most amateurs who are interested in local communication over a few miles using surface waves don't need to see the overall elevation pattern, and they can get numerical results of the surface field strength from the near field analysis. Amateurs communicating by sky wave, by far the more common situation, can benefit from the graphical results afforded by

EZNEC's far field elevation pattern.

Not that there is
> anything incorrect with Eznec. It is just the confusing description
> of what it displays.

It's interesting that in the 15 years EZNEC and its predecessor ELNEC have been available, and the thousands of users, no more than a half dozen people have expressed any confusion regarding its far and near field analysis. And none of the others has required repeated explanations. But some people are sure to have more trouble with the concept than others.

It's explained in the EZNEC manual, and I always welcome questions and suggestions which would help me make it more clear. I am, however, resigned to the fact that some small number of people aren't capable of, and some simply aren't interested in, understanding.

Because of your deep interest in surface wave propagation and field strength prediction, and your characterization of it as "often-used", you must do a lot of communication by this mode. What bands do you use, and what sort of range do you reliably communicate over? How many hams are within this radius whom you talk to?

If you really want to have the "mast" unsupported, consider a 50-60'
telephone pole
properly installed (for your type of soil) with one end buried deeply.
Perhaps you could
use a fiberglass extension from its top to support the antenna.

It would be worth your while to have a mechanical engineer calculate your
design's survival
characteristics in high wind and compare it with 100 year records for high
wind speed. Also you
might consider the prospect of icing if you live in a northern climb -- I
assume that the mast
is at a corner of the loop.

The stub is a good idea and can be mechanically self-supporting at
920 MHz. However, making the bottom section 1/4WL (as Kraus suggests)
instead of 1/2WL would make for a low feedpoint impedance

Google "used books". I've had good luck with
www.abebooks.com

I have also run across foreign published books that
are about half priced and new. Don't recall the URL.

But I've given you all the information in Kraus' book
about that particular antenna. Laid on its side:

```
|
|----------/////--------------------
| 1/4WL coil 1/2WL
```

The coil is a 180 deg. phase reversing coil. If I
remember correctly, that means it is self-resonant.
If that's right, it probably means that a trap
would work instead of a coil. The impedance at the
bottom and top of the coil is very high so it seems
to me that instead of blocking the signal, like an
ordinary trap, a trap would merely reverse the phase.

I am not sure I understand the question. I think you have the rotator upside down on the tower at the moment. If it went through some weather, it is probably full of water now. The way I would handle the problem is to remove the rotator from the mount and hang it on the tower (clothes hanger wire) right side up. I would hang it there for a few days to drain & dry out. When it comes time to reinstall the antennas, test the rotator for proper operation. Chances are that it will be OK. If you seal it tight, the moisture will be sealed in. These things are intended to be able to breathe!

If removing/replacing the rotator is a major hassle, I would either send it to one of the maintenance guys or put up a new one & sell the old one on ebay WITH the explanation. There are lots of us who have setups that are easy to change.

If the rotator must be left in the inverted position outside for an extended time I would wrap it in black landscape plastic and duct tape to prevent more water from entering while leaving the bottom of the plastic open to dry out.

The tower is currently up (the mast broke above the rotor, so all the antennas are dangling by their feedlines, but the tower itself is OK) and the rotor is in its normal upright position. It will be upside down when the tower is folded over to work on. As far as I know, the rotor is fine right now.

> If removing/replacing the rotator is a major hassle, I would either
> send it to one of the maintenance guys or put up a new one & sell the

> setups that are easy to change.

Don't understand this. Yes, removing/replacing the rotor is a hassle, largely because it has to be done with the unit upside down, and standing at the top of a ladder. But that isn't the issue here - in fact, there is no obvious reason to remove the rotor at all, since it seems intact. Just remove the stub of the broken mast from the thrust bearing and put a new one in. The issue is that while that is done, and the new antennas are mounted, and new (or repaired) feedlines are run, and all the antennas are tuned, the tower will need to be folded over, with the rotor mounted, and these steps will almost certainly take several days. Because of availability of helpers reasons, this will likely have to be on weekends, meaning the tower will be folded (and the rotor inverted) for a period of at least 1 to 2 weeks.

I have done this in the past, but because of the way the rotor is mounted on the Rohn tower, it isn't possible to seal it very well this way - I was looking for suggestions for better ways of weatherproofing it for this period.

Can anyone comment on a comparison between these two rotors?
I'm looking to purchase one or the other, and need something to tip the
scales.

tnx,

Have you deffinantly got the antenna power line connected to the head unit. On an ISO radio connector this is a blue wire which provides power to an antenna amplifier found on some cars.

Make sure you've fitted the earth (ground?) bar from your radio to the car's body (for example the bolt that holds the radio cage in).

Try using a different antenna to see if the problem re-occurs.

Did they start making the HD73 again? I thought they stopped that about 20 years ago. I still have one on my UHF antenna, bought the HD73 in 1979. My main rotator is a Yaesu G1000. You get more for less with Yaesu. Really nice control box.

Dave -

This is a FAQ regarding rotators mfg. in USA.
The HD-73 was made by Alliance (Alliance, Ohio) and the Ham-M series by CDE.
http://www.rotorservice.com/index.htm
====
Alliance stopped production of their rotors in 1994.
Norm's Rotor Service (NRS) purchased their entire parts inventory for the
HD-73, U-100, and U-110 rotors and controls. NRS was recently purchased by a
group in Alabama.
====
The Cornell Dubilier Electronics company sold their rotor division to
Telex/Hy-Gain in 1981. Hy-Gain decided to support only the AR-22, AR-40,
CD45-II, Ham-4, and Tailtwister rotors. All rights to the other rotors were
assigned to Norm's Rotor Service.
Today NRS is the only facility with parts for these CDW or HyGain original
units (not in current production).
NRS has almost all of the parts for the AR-22, AR-33, AR-40, AR-50, BT-1,
TR-44, CD-44, Ham-M, Ham-2, and Ham-3 rotor models.
Telex/HyGain sold the HyGain line of rotors to MFJ in May of 1999 (NRS have
parts for these current US production rotors that Hy-Gain continues to
support.).
====
The Ham-M rotor was released in 1957, and there were 5 series with the last
rotor being produced in 1973. The Ham-M rotor would have the series number,
1 - 5, followed by 3 digits which indicated the week and year of
manufacture. For example, a rotor with the series number 5 322 would be a
Ham-M, series 5, manufactured in the twenty-second week (the '22' in '322')
of the year 1973 (the '3' in '322').
A Ham-M has a single-levered control box with a meter. In 1973 the mold for
making the Ham-M control unit shell was destroyed in a fire. So rather than
spend the money to replace the mold, the Ham-2 was born. The rotor was the
same as the Ham-M, but the control unit was replaced with a three-button
unit with a continuous meter reading.

In 1977 the Ham-3 rotor was released. The Ham-3 supported a new motor with an internal brake, as well as a brass motor gear. The brake wedge was redesigned, as was the brake housing, which gave the new unit a capacity for more wind surface area. The control unit for the Ham-3 supported a new PC-board-mounted meter.

In 1978 the Ham-4 or Ham-IV rotor was released. This rotor had a new steel ring gear and a reinforced upper mast support. The only changes to the control box were the addition of a new face plate, plastic top and bottom covers, and a new meter with reversible meter scales. Also in 1978 the Tailtwister rotor, commonly referred to as the "T2X," was introduced. The T2X is a Ham-4 with an even heavier upper mast support, a heavier brake wedge and brake housing, and 40 additional ball bearings. And the Tailtwister control unit has three LED's that the Ham-4 doesn't have.

I second that motion. At $28.50, it is about 1/2 the cost of mine which was a bargain at that. Kraus` "Antennas" is without peer. As Kraus is now dead, there won`t likely be a new improved edition as in the past.

Best regards, Richard Harrison, KB5WZI

Dave,

If you read his shopping list you see that his drawing is wrong. The _TOTAL_ length of the small pipe is 1480. Still a vertical half wave radiator.

I see no one took this part so I will address the question of what these antennas are, but second. I also read your later post describing your application very well and make this comment first.

If you want to simply 'build' the antenna from physical dimensions derived from another frequency or antenna or just from "scratch", I see two significant problems.

One is that if you have no measuring equipment for 915 MHz, you run a real risk of not getting the size close enough regardless which type of antenna you choose. This could wipe out all your desire to get "reasonable gain". While RF is commonly called "Black magic" there are strays that can be understood only to some extent and therefore they can easily get you off your target. The other is that the plastic "Radome" *will* have an effect on the resonant frequency (lowering the frequency), so comparing it to an "open air" version moves you off your target as well. A common issue relating to both of these is that as you make an antenna with more and more gain, the dimensions become more and more critical to get the best performance.

As a conclusion to this I would recommend setting up the system with a simple, good old quarter wave ground plane and see if you really need "reasonable gain".

Now, on to the "what-is-this-antenna" question you asked earlier. A "J-Pole" (or as I consider, more correctly) a "J" antenna is a vertical half wave antenna (radiating element). It is fed at the bottom (end fed) with an approximately quarter wave long, shorted line, or matching section, or matching stub - call it what you wish. This matching section is constructed of open, parallel wire transmission line. The match to 50 ohms is obtained by connecting the feed line to a point on the matching section closest to 50 ohms. As a simplification you can look at the classical quarter wave shorted stub. Where the impedance goes from zero at the shorted end to a

very high value at the open end. Connecting the high impedance (end of the) half wave radiator to the high impedance end of the stub leads us to conclude that we ought to be able to find any impedance we want (between "high" and zero) somewhere along the length of the stub - and we basically do.

. The length of the matching section and the point where the t-line connects both can be adjusted to get to the best match - though this may not be easy given the construction method used. It is called "J" because when you put the matching section in line with the radiator (and there is nothing requiring this) it has the physical shape of a "J". The matching section could be at right angles to the radiator destroying the "J" shape and the concepts described here are the same (there are antennas done this way). I described it as I did so I can replace the open wire matching section with a coax matching section of the same properties and get the Sperrtopf antenna exactly. So the Sperrtopf can be called a "Sleeve J-Pole" if you like. Or, for those enamored with the "pole", perhaps a "Sleeve-Pole".

The "sleeve" antenna, or "sleeve dipole" I also a vertical half wave antenna, but it is center fed . Start with an ordinary half wave, center fed dipole. Turn it vertically. Feed it with coax (yes, I know there is a balanced to un-balanced issue, but stay with me). Now, convert one half of the dipole (one quarter wave length side) from a wire to a pipe. Make this the half which has the coax shield connected to it. Then, take the coax and rather than running it away at 90 degrees, stuff it down the center of the pipe, out the end and to the transmitter. This is the sleeve dipole. Some may consider the sleeve simply to be a "choke" keeping current off the t-line and there are usually several models which can be used to explain one configuration.

The referenced Microwaves article shows one type of these, the ordinary sleeve dipole. Looking at Fig 3 and the Appendix B picture, Antenna 3 is clearly the classical vertical sleeve dipole.

If I read this correctly, the sleeve dipole closely mimics the ordinary dipole as one would expect. The "spaced gap" antenna (#2) appears close with possibly a little less gain due to the flattened pattern (more radiation at 30 & 150 degrees). Either the #2 or #3 look like they are easy to construct, with the cautions I mentioned above.

Finally, the antenna you described taking apart, looks to me like the #1 antenna (Extended Inner" with a choke 1/4 wave back from the shield end. Too bad the Microwave paper didn't try this.

Yep and this makes it a "phasing" coil and the antenna a colinear. The phasing coil causes the current in the two sections of the antenna to be in phase. Note my addition of polarity indicators to the above diagram. The right end of both elements are the same = in phase currents. Now you have a half wave and a quarter wave in phase, yielding gain by a flatter pattern (whicn is vertical in this drawing).
You can stack half waves up like this and this is done in common cellular gain antennas - probably WiMax as well. There are several ways to do the phasing... Coils like this, quarter-wave shorted stubs (parallel-line), reverse connecting alternate sections of coaxial t-line as elements, phasing harnesses on the feed line... Probably more.

Source record: 70547

Last year I moved my antenna mast system to the 'south' side of my house. Right off lighting 'busted' a two meter/440 ground plane. The 'juice' came in the shack, by way of two antennas, a TV antenna/coax, and the coax for the 2/440. I had the coax un connected to the radios. The TV antenna's coax was connected, to a monitor/TV and VCR,,, ''they bit the dust''.
I had almost this same system on the north side of the house for many years, with no apprent damage/problems. I have re purchased new antennas and installed them in the air, several months ago. We have had some 'near misses' since then, I no longer have the TV antenna on the main mast (75'), it is located nearby now at about 20'.
I don't know why, after 'the move south 100' I have more problems with lighting. I want to add more assurances (gournds?) to the system, including a antenna switch, that has in it a swithch to "ground".
But I don't feel really comfortable, putting some of my eggs in this 'ground switch basket'. I purchased some connectors that ''slip on, slip off'', and I am thinking of adding a panel with these slip connectors monted close at hand, and when there is "weather" I just pull the slip connectors lose, and then use the ''ground switch", switching, to ground.
Soooo now my question, how many '''holes''' are there in my ideas/plans???? thanks in advance. cl 73

I would like to express my appreciation for all those who have taken the time to respond to my post. Being new to antenna design and construction I understand some of my questions and comments may seem a bit "silly" and it would be easy for people to suggest that I go learn more first or simply use trial and error.

I have a practical requirement for a flexible whip antenna that results in "good" gain that works but at the same time I want to learn what I can because it is my intention to later experiment with other style of antenna (Yagi at 434MHz is next on my list).

Now, back to the 1/4 wave, phasing coil, 1/2 wave design.

Does this means for a practical antenna I could have...

SMA plug centre pin -> 1/4 length of wire -> several turns of wire around the Radome -> 1/2 length of wire ? (ie. coax earth braid stops at SMA and rest of antenna is made up of inner conductor and dielectric only).

Is it that "simple" ? If so, that would be easy to construct in a flexible whip (which is my aim) compared to many of the other suggestions.

Is the gain the same as a dipole ?

Also, I have EZNEC 4. but have not had a chance to learn it yet. Can you model the coil in the program or can you only enter segments ?

Thanks.

It's bad enough that people feel a need to believe in any deities at
all, but when you have to listen to a bunch of old men in robes half a
world away tell you how to live your life, you're pretty screwed up.

The non-simple part is designing the 180 deg. phase
shifting coil. I think I have one of those on my
Diamond mobile antenna.

> Is the gain the same as a dipole ?

Higher than a dipole - close to 6 dBi compared to the
1/4WL ground plane at *about* 0 dBi.

Richard

I'd have expected the "gain" to be closer to 4 1/2 db over the 1/4 wave
stub over a ground. is it easy to show where i've missed something?

What is a 'terminated dipole'?
And why 600-800 ohms?

No, Mine will be just a normal dipole (but long). I'll be in a
spaceship, miles from anywhere, and I intend to put out a really long
antenna so I can work the universe on all amateur bands. (I don't care
about the polar diagram - there's bound to be someone out there in one
of the major lobes).

I intend to throw out an infinitely long wire either side of the ship,
and use a balanced tuner connected directly to the antenna (no feeder
required). Because of weight restrictions, I can only take one tuner,
and I want to make sure that the one I do take will cope with the feed
impedance of the antenna.

I think the impedance will be the same at all frequencies (maybe even at
'zero Hz'). But what will it be?

Ian.

I have constructed a 915 MHz 1/2 wave, end fed antenna that fits onto
the end of a SMA plug based on help from you guys. I have some pics of
the construction if anyone is interested in taking a look.
Where is the appropriate place to post these jpg files ?

I am accessing this newsgroup from my email client presently.

I am not sure how I can optimize this yet. My antenna Analyzer is the
MJF unit that only goes to 440MHz.

I have a 1GHz spec analyzer, 1GHz Sig Gen and a Telonic VSWR kit that
goes to 2.5GHz but I think the drive required to the VSWR "Rho-Tector"
needs to be higher than the 10dBm from the sig gen.

Could I optimize the design with this equipment, or maybe would I be
better to use RSSI levels from a receiver placed say 3m away from
Antenna under test ?

If the antenna works I will be very excited as it is very simple to
construct in around 10 minutes and at a cost of around $3 (no counting
labour).

Thanks for any help.

Now I understand!
I this case I would get some of the soft rope like window putty from the hardware store to seal up the rotator while it was vulnerable. I have not bought any for years, I assume it is still available. Play Dough does not work well, it either shrinks and falls out or hardens.

Extra ground rods are good but they must ALL be tied together with at least #6 copper wire. A 300 foot roll of bare #6 copper wire costs about $69 at my local home improvement store.

I am not an expert, but I have more than my share of bad experience!

I lke my Yaesu rotator but a lightning strike while still in warranty
nailed the control box and the US distributer offered no solution
other than buy a new rotator.

Fortunately, a homebrew control box is pretty simple.

Ian Jackson wrote:
> What is a 'terminated dipole'?

In an anechoic chamber, the dipole has a resistor to chassis at
both ends. When the value of the resistor equals the characteristic
impedance of the dipole, the dipole becomes a traveling wave
antenna instead of a standing wave antenna. Your infinite dipole
in free space will be a traveling wave antenna, i.e. no reflections.

> And why 600-800 ohms?

That's a ballpark Z0 for traveling wave antennas not located
near ground. It's the Z0 of a 1/2WL dipole during the transient
state before the arrival of the first reflections from the ends.

The resonant feedpoint impedance of a center-fed 1/2WL dipole is
(the difference between the values of the forward voltage and the
reflected voltage) divided by (the sum of the values of the forward
current and reflected current). Note: the two voltages are out of
phase and the two currents are in phase.

This is the (B) definition of "impedance" in the "IEEE Dictionary",
i.e. impedance as a *result*, not a cause. Destructive wave interference
at the feedpoint of a center-fed 1/2WL dipole is what causes a Z0-match
to a low resistive value, e.g. 50 ohms or 70 ohms.

You need the good ground at the base of the antenna/mast.
Adding "grounds" to switches, etc, are generally a waste of
time. Being grounded, does not mean being safe. In many strikes,
it's the grounded stuff that takes the most damage. I would ground
the supporting mast with a good ground rod, etc, and use normal
lightning suppression methods to protect the gear in the house.
IE: suppressors, etc.. Check out polyphaser, etc..

> What is the impedance at the centre of an infinitely long dipole
(in
> free space)?

==========
Its not very different from -

Zin = 120 * Ln(Wavelength / d) ohms.

where d = conductor diameter, both measured in metres.

Thus, at wavelength = 80 metres with 14 gauge copper wire, input
impedance = 1300 ohms approx.

If you don't believe me, just measure it.

Reg.

I just purchased a Ten-Tec 1208 Transverter to get my feet wet on six meters. I would like to use my existing W9INN fan dipole if possible. At the present time the fan dipole has three sets of wires from the common feed point for 40/80, 10 MHz and 18 MHz. My plan is to add another short set of wires cut for 50.125 MHz. Since each of the new wires will only be 4.67 feet, I plan to use stand offs and run them close to the 40/80 dipoles. It will be interesting to see if this really works. Any suggestions for the short stand off insulators?

Any suggestions on how to keep the new six meter wires from wrapping
around the 40 meter wire in the wind? My plan sounds good until the
wind blows and I have visions of the short six meter wires getting
tangled in the other wires. I would tie them off with additional tie
ropes but it would wind up looking more like an extreme Inverted V
antenna.

18 MHz times three equals 54 MHz. The 18 MHz dipole is likely to
detune the 6m dipole. See what the 6m SWR is now. You may not
need any additional wires.

Cecil

He is feeding the 1/2 wave antenna in the center, where the impedance will
be somewhere around 70 ohms. His coax feed line is located within one half
of the antenna and exits the 1/2 wave, center excited, dipole at the "high
impedance" end of the dipole.

David sent me some pictures. The antenna looks quite good.

The effectiveness of the "choke" that attempts to disconnect the dipole
from the feed line may be less than ideal, but it is yet unknown how good
this antenna needs to be.

Jerry

677. help requested for designing 4-square inverted L on 20 meters

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-17 18:55:16 UTC
From: eternalsquire@comcast.net
Message-ID: <1126983316.093491.307380@g43g2000cwa.googlegroups.com>
Source record: 70574

Hi,

I am using 4nec2 and ICEPAC to design a 4-square inverted L. I think the far field pattern, SWR, and area coverage are pretty good. I believe most receivers can hear signals down to -120db fairly well. I am modelling not only radials but also a ground system to reduce the SWR and help with the lightning protection. I hacked this out of a standard 4-square for 80 meters.

Any of the 4-square people out there who can offer additional pointers, construction details, and other things I have not considered? I'm finding trouble reducing the SWR from 2:1 down to 1:1

NOTE: Distance T is an arbitrary distance between the ground and a planned wooden deck roof to help disguise the system. Distance D is an arbitrarily small distance between the ground system and the dirt.

Thanks much!

The Eternal Squire

You would think so, since 7 x 7.2 = 50.4. I happen to have a 7 & 18 MHz antenna; so, I measured the SWR on 6 meters. Got about 2.9:1 at 50.25. SWR at 56 MHz is about 1.2:1. Nevertheless, I have spoken to people on 6m who were using 40 m dipoles.

don't worry about the swr, you need to build a phasing system that generates
the required feed currents and that can easily contain a network to bring
the output impedance to whatever you want to feed it with.

also, why bother with inverted L's? a full 1/4 wave vertical for 20m is
only about 15' tall, easily built from tubing or pipe and easily supported
even free standing.

Good point. I may hold off until I get the Ten-Tec 1208 and see what I
have with the existing mess of wires. HiHi

I don't have an antenna analyser so will have to wait until I generate a
six meter signal.

Anyone ever tried six meters on an old Ringo Ranger 2 meter antenna?

Dick AA5VU

>>
>>
>> Not at zero Hz.

Now#1, an infinitely long wire has an infinite self inductance.
Now#2, an infinitely long wire has an infinite self capacitance.
Now#3, frequency does not enter into the equation

Zo = SQRT[L(infinite)/C(infinite)]

Now, from my old college days, infinity divided by infinity is
undefined. The SQRT of an undefined value is by definition undefined.

Conclusion: the impedance of an infinitely long wire in free space is
not the SAME as a terminated dipole in an anechoic chamber.

NOTE: an infinitely long wire in free space cannot be terminated. A
terminated wire in an anechoic chamber is not the same as a free space
model.

A terminated wire in in an anechoic chamber is a standard math model
with Zo varying as the ratio of the wire diameter and the distance to
the 'space cloth/cones' [which are not perfect rf absorbers ... hence
some reflection]. Also, the termination destroys the symmetry.

It should work OK. You will need a little patience to prune the 50 Mhz antenna length to resonance.

To reduce the coupling between antennas you could allow the 50 MHz dipole to droop a little in the form of a shallow inverted-V.

Just progressivly increase the lemgth of the hanging insulating strings towards the end of the 50 MHz dipole. It doesn't matter if the dipole has curves in it.

I hope I have correctly judged your setup.

Reg.

I think it should be more like 3 dB, but hadn't said anything until I had a chance to model it. The quarter wave stub doesn't radiate significantly, so it can be ignored. A half wavelength element should have about 1.5 dB gain over a quarter wave. Two of them would give another 3 dB if it weren't for mutual coupling, but the mutual coupling of collinear elements reduces the gain to about 1.5 dB over a single element. (See for example Fig. 39 on p. 8-35 of the ARRL Antenna Book, 20th Edition; look up Collinear, Gain and directivity in the index of other editions; or model it with your favorite program.)

You had better go back to your old college days and start again with new teachers.

The input impedance of an infinite dipole is as I have already simply mathematically described. It changes a little with frequency and wire diameter.

Anything less than infinite length will be altogether different.

Now you can stop trying to pull our legs.

Thanks Roy

Your posts always add alot to my understanding. I appreciate your taking
time to evaluate this antenna and then pass the information on to the group.

Jerry

I'm sorry, I see I wasn't clear in saying that I haven't yet had a
chance to model it. There might be a flaw in my reasoning, and the
antenna might have more gain than I think. I'll try to get to it as soon
as I can -- unless someone else wants to take it on. But I'm extremely
busy just now.

Not exactly the same but close enough for government work.
Reflections from the ends and from the walls are reduced
to a negligible value. Been there, done that.

The ringo ranger is vertical and most 6m stuff is horizontal. On skip
that may not hurt but for local it's very poor.

I worked Canada on 6 meters with that transverter. Used a trapped dipole
for 40 to 10 meters.

I doube the ringo would work on 6 due to the way is fed. If it was just a
baseloaded (matched) 5/8 wave 2 meter antenna, it might work fine.

That 17m (18mhz) antenna should do well. I run a bunch of antennas
and for local work rather than turning a beam I use a `24ft EDZ with
a stub tuning on each wire to match 50ohms. The oddity of that
antenna is it looks like a plain dipole at 18mhz according to the
MFJ269b.

I'd drive that and see what the SWR looked like, it may be fair
as is. Owing to the amount of wire it may offer some amout of gain
over a plain dipole.

Good luck,
Allison

Take a look at the far-field pattern and you'll see why I want it.
Also, it seems that inverted L's rather than verticals lower the
SWR from the thousands to something more sensible.

The Eternal Squire.

The feedpoint SWR will depend heavily on the type of feed system used. The 4SqTL.EZ example model included with EZNEC, which uses one of the all-transmission line feed systems described by "The Simplest Phased Array Feed System - That Works", shows a 50-ohm SWR of 3.7 at the feedpoint. Other feed systems are possible using this method, each of which produces a different feedpoint impedance. The combination transmission line - L network method described in Chapter 8 of the ARRL Antenna book produces yet other feedpoint impedances, depending on the transmission line Z0s which are chosen. There's no need to settle for a feedpoint SWR in the thousands, and there's no need to alter your array elements as a means of improving it.

If you use inverted-L elements for a four square array, it seems to me you'd get a different elevation pattern in the various directions, and that the azimuth pattern would be distorted by the directionality of the elements. Have you modeled the full four element array, with the currents phased as they would be for each of the four readily switchable directions?

I have decided to hold off changing anything until I get the Transverter
next week. I will then see if someone is close before I start messing
with extra wires.

The problem with adding another set of wires for 50.125 is how to keep
them from getting tangled in the wind. I have visions of them wrapping
around the 40/80 set of wires.

Stay tuned for what happens. Half the fun of getting a new toy like the
six meter transverter will be finding the right antenna.

Dick aa5Vu

Don't give up on the vertical too quickly. I use both a 6 meter dipole and a 6 meter J-pole, 90% of my 6 meter contacts have been with the J-pole. Some of the more experienced Hams of my acquaintance have told me that DX sort of works outside of the normal vertical/horizontal polarization expectation. I rarely have any occasion for a local 6 meter
contact. so am not able to speak about that aspect of the 6 meter band.

Roy,

I am using your EZNEC V4.019. Would you happen to have the ez
description file for this antenna so I can see how it is modeled ?

I had a "play" and set up 2 vertical have wave lengths and set the
source at the centre I then placed a 1/4 wave wire near the lower
1/4 wave and connect them at the centre point with a horizontal wire but
the program kept complaining that the wires were overlapping etc.

I also tried modeling an open stub J-Pole and seemed to be able to get
some plots that look ok but SWR was >100 across the band. Not sure what
I did wrong here but I assume as I get more familiar with modeling
techniques, I will get more meaningful results.

Thanks

Regards

David

Sorry, I haven't had time to model it. But I dusted off a very old, originally ELNEC, model of a 3 element collinear, and uploaded it to my web site. It should give you the general idea. It's Collinear3.EZ at http://eznec.com/misc/.

| is as I have already simply mathematically described.
| It changes a little with frequency and wire diameter.
|
| Anything less than infinite length will be altogether different.
|
| Now you can stop trying to pull our legs.
| ----
| Reg.

Dear Mr. Reg Edwards,

This is an interesting question indeed!

Well,
my wife yinSV7DMCdag has developed sometime an AVI movie

[ in ZIP form:
[ http://antennas.ee.duth.gr/ftp/visualantennas/thedipole/films/fu010100.zip
[ 850 KB

which deals among other properties of a filamentary dipole,
with its Radiation Resistance relative to the Input Terminals (Driving Point)

[ Please take a look if you like
[ in the part D of the movie,
[ at the bottom right of the screen

This is actually the Input Resistance Rinp
of a filamentary dipole of perfect conductivity in free space.

The ratio of dipole length L to wavelength lambda takes values up to 10,
but someone may maintain arguably that either
the limit of Rinp exists in general as infinity or does not exist at all.

Yours Sincerely,

pezSV7BAXdag

Are you sure it's as high as that, Reg? I once did a Smith Chart plot of
the impedance at the centre of a dipole, the valued being taken from a
table 'compiled by Wu' (LK Wu?). These only catered for a lengths up to
a few wavelengths. As the plot progressed round and round the Smith
Chart, it seemed to be heading for something around 350 to 400 ohms.

I've just done a search on 'Wu+dipole+impedance', and one of the results
is
http://www.fars.k6ya.org/docs/antenna-impedance-models.pdf
I'll have a read of it today.

Cheers,
Ian.

Just heard mention of the EH Antenna and that it is rather small but equal radiation to a full size dipole !!!.

If this is true, i am very interested as i only have a small garden (35x18 feet) and the EH sounds ideal so anyone with info , it would be greatly appreciated.

I am using a homebrew helical for 80m and a sloping half size G5RV and i am really stuck for space :-/

The open stub J-Pole (Zepp) is modeled as a shorted stub
J-Pole with the source in the middle of the shorted segment.
Mine is for 53.2 MHz. On edge it looks like this:

```
13.5 ft.
+-------------------------------------------------
|
(S)
|
+-----------------
4.5 ft.
```

The sections are 0.1 ft. apart. The resonant frequency is
53.2 MHz and the feedpoint impedance is 25 ohms for an SWR
of 2:1. The feedpoint is 30 ft. high over high-accuracy
ground. The gain over ground is 6.2 dBi, omnidirectional.
Free space gain is 3.4 dBi.

Anyone who wants a copy of this 6m J-Pole EZNEC file, please
send me an email to mycall@arrl.net.

You can vary the feedpoint impedance by changing (S).

Hello Lee,

The EH antenna is a hoax perpetrated by somebody who hopes to make money by selling them. His sales description of how the thing works pretends to make use of the mathematical works of James Clerk Maxwell. It may sound good to novices but is just a load of nonsense.

Actually, its performance is somewhat worse than other antennas of the same physical size.

If it's claims are as marvellous as all that, ask yourself why every amateur doesn't have one, regardless of how big is his backyard. To a smaller extent, the G5RV falls into the same category.

You did right to ask your question.

Reg.

Maybe 377 ohms? Remember that any finite length dipole is a standing
wave antenna and the feedpoint impedance is (Vfor+Vref)/(Ifor+Iref)
where Vfor is the forward voltage phasor, Vref is the reflected
voltage phasor, Ifor is the forward current phasor, and Iref is
the reflected current phasor.

For a 1/2WL resonant dipole the feedpoint impedance is low:
R = (|Vfor|-|Vref|)/(|Ifor|+|Iref|) ~ 73 ohms

For a 1WL (anti)resonant dipole the feedpoint impedance is high:
R = (|Vfor|+|Vref|)/(|Ifor|-|Iref|) ~ 5200 ohms (EZNEC)

An infinite dipole would not be a standing wave antenna. It would
be a traveling wave antenna (as in a terminated rhombic). So the
feedpoint impedance of an infinite dipole would be Vfor/Ifor=Z0.
Since the reflections modify the feedpoint impedance, we might
suspect that Vfor/Ifor falls between the feedpoint impedance for
a 1/2WL dipole and a one WL dipole. Seems to me, the Z0 of the
dipole, i.e. Vfor/Ifor, must be in the ballpark of the square
root of the product of those two feedpoint impedances.

The 73 ohm radiation resistance value applies to a physical 1/2-wave, thin-wire, linear dipole in free space, however a reactance term of + j42.5 ohms also applies to such a configuration (Kraus 3rd Edition, p. 182).

The dipole length needs to be shorted by several percent in order to zero out the reactance term, at which time (according to Kraus), the resistance term will be about 65 ohms.

Moving the elements to one foot apart increases the
feedpoint resistance to about 50 ohms at resonance
but it decreases the gain and distorts the radiation
pattern since one foot is an appreciable distance
on 6 meters.

Experience is that my vertical beam hears far less DX than the
horizontal. Occasionally I hear DX on the Vertical that is better
but on confirming the other end is also vertical. So it goes.
I do have vertical for those times where it may help. One thing I do
notice is the noise level of the vertical beam is far worse.

For local use the horizontal is usually 2-3 Sunits higher than the
vertical.

==========

A back-to-back horizontal helical dipole is a good proposition.
Radiating efficiency is what matters with physically small antennas.
The radiating pattern is whatever you happen to get.

A 1/2-wave helical resonant dipole is considerably more efficient than
a 1/4-wave vertical simply because of the absence of ground connection
losses.

A low dipole does have a small ground loss due to its proximity to
ground. Ideally its height should be at least equal to its overall
length but half that is a satisfactory compromise.

A horizontal helical dipole is the same as a centre-loaded wire with a
very long loading coil. It is easier to match to a feedline than a
vertical and there is a choice of type of line and line impedance.

Either coax or balanced line can be used. Make the loading coil
continuous through the antenna centre and enclose the centre with a
link coupling to the feedline. The number of turns on the coupling
link is dependent on line impedance.

The antenna itself is electrically isolated from the line and remains
nicely balanced about ground.

The greater the diameter of the loading coil former, a rigid plastic
pipe, and the thicker the wire, the higher the efficiency. For 100
watts transmitters, close wound turns of thick enamelled wire are
usually OK.

Resonant frequency is adjusted by pruning the length of the wire or
rods which extend beyond the ends of the coil. If essential due to
space limitations, the end wires can be allowed to fall down towards
the ground but not allowed to swing about in the wind.

Short loaded antennas are essentially single frequency, very narrow
bandwidth devices.

Download program MIDLOAD from website below. It may be of assistance
or at least provide you with something to think about.

In postage-stamp backyards, size-for-size, Magloops are the most
efficient of all very small antennas and can cover several adjacent
bands, but are deceptively difficult/easy/expensive to construct
depending on your ingenuity. Download program MAGLOOP4.

Yes, I did think of 377 ohms (which I understand is 'the impedance of
free space'), but I'm no expert in these matters.

As you indicate, the impedance must lie somewhere between 73 and 5200
ohms. You suggest that this might be something like the square root of
the product of those two feedpoint impedances (the geometric mean),
which gives 616 ohms. However, you would see 600 ohms simply by looking
into an infinite length of 600 ohm feeder, which has parallel,
non-radiating conductors. If the length of the feeder was relatively
short (compared with infinity!!), pulling the conductors apart would
increase the impedance (probably to a lot more than 616 ohms). The
question is, 'when does radiation start to influence the impedance?'

If you look at K6OIK's paper at
http://www.fars.k6ya.org/docs/antenna-impedance-models.pdf
and look at, for example, page 22, you can see how the feed impedance at odd halfwaves increases, and at even halfwaves, decreases. I only found this paper this morning, and haven't had time to look to see which (if any) of the many formulas was used to obtain the plot. It must be possible to get close to the infinity condition by entering values for a very, very long dipole.

Cheers,
Ian.

Didn't Radio 252 (252kHz) near Dublin start out using an E-H antenna?
And wasn't there a new high-power SW station in Egypt which was supposed
to use one too? I've feeling that with the latter, they pulled it down
and used a conventional antenna.
Ian.

Yes had a look at that one, gave me a few ideas as i like constructional projects.....You`ve given me a lot to think about Reg, it`s either a helical dipole or a magloop ..... there is a helical 40mtr beam in the ARRL handbook i`ve been looking at too....

Thanks .

Lee.

Before somebody tells you that polarization is unimportant for a skip signal, your 6 meter observations parallel what I found on 40. I had a 40 dipole and 40 GP vertical. In round table test with stations 400 - 800 miles away, people with verticals preferred my vertical, and people with dipoles preferred my dipole. There were a few people who could not tell the difference.

In King and Harrrison's _Antennas and Waves_, they show a plot of calculated antenna feedpoint impedance as X vs R up to about 5 wavelengths. Antenna wire radius is 0.008496 wavelength. The Z of an infinite length antenna is indicated by locating the centers of the circles and noting that the center converges. The point of convergence for this particular wire radius is about 250 - j170 ohms.

In the chapter on experimental measurements, there's a plot of the calculated admittance of an antenna of radius 0.000635 wavelength up to about 10 wavelengths. Superimposed are measured values from another source which show very good agreement. The theoretical values converge at 214 - j189 ohms, and the measured values at 218 - j174 ohms.

Dervivation takes about a chapter of very heavy math, and numerical results were obtained with a computer.

Ian Jackson wrote:
"Maybe 377 ohms?"

Arnold B. Bailey in "TV and Other Receiving Antennas" shows his calculations of radiation resistance at the current maximum point for a center-fed thin dipole at its various resonances:

1st----------72 ohms
2nd----------200 ohms
3rd----------102 ohms
4th----------260 ohms
5th----------117 ohms
6th----------295 ohms
7th----------127 ohms
8th----------321 ohms
9th----------135 ohms
10th----------340 ohms

He also shows the current distributions and feed point resistances which I can`t and won`t.

The input resistance of the center-fed antenna at resonance never equals the surge resistance in value, but is related to it.

Best regards, Richard Harrison, KB5WZI

That model seems to work fine in EZNEC.

I tried a 918 MHz version with long length = 219mm, short length = 72mm,
24mm apart, 1.5mm solid aluminum construction.

The results show excellent SWR and feedpoint impedance close to 50
Ohms.(50.29 -j0.0148), SWR = 1.006
The unit is not so omnidirectional showing a front/back ratio of
5.79dB.(Beamwidth 214.4 Degrees).

The maximum gain was 4.74dB(ref) at 4 degrees (elevation). dB ref =
2.14dBi so I suppose this is saying gain is 4.74dBd.

That's pretty strange. The only ready explanation is radiation from the transmission line section. Apparently it's significant with the 0.074 wavelength conductor spacing.

> The maximum gain was 4.74dB(ref) at 4 degrees (elevation). dB ref =
> 2.14dBi so I suppose this is saying gain is 4.74dBd.

If the antenna is in free space, the currents in the elements are exactly in phase, and the transmission line radiation is negligible, the gain should be maximum broadside to the antenna, not at 4 degrees elevation. So one or more of those conditions isn't true. The horizontal directivity indicates that the transmission line section is radiating, but I wonder also if you might be modeling it over ground.

The gain is 4.7 dB relative to a dipole in free space. If you're modeling it over ground, the gain isn't 4.7 dB over a dipole at the same height above ground, which is why I dislike the term "dBd". (But antenna manufacturers who can capitalize on the ambiguity love it.) If you're modeling it over ground and want to know the gain over a dipole at the same height, model a dipole at that height and compare gains.

Open the EZNEC file. In the main window, click the Wires line to open the Wires Window. Find the Diameter column, where you'll see the diameter of each conductor.

The equation you give is approximately the characteristic impedance of a transmission line, not the feedpoint impedance of a J-pole. The relationship between the two is very tenuous and complex.

Roy,

The model I used for the open stub J-pole was not the same as your 3
element col.

I used a vertical long element and vertical short element. They were
joined by a horizontal element at the base. The source was set at 50%
along the horizontal bar as per your diagram.

I changed the model for free space rather than over real ground but this
has not helped the directional aspects of the plot.

The dimensions were scaled form those shown for a 150MHz open ended
J-pole shown on Arrow Electronics site

http://www.arrowantennas.com/j-pole.html

A wooden utility pole with a length of 40 feet above ground would do the job for me. It's just that I am not sure how the neighbors would react. A search of the web did show that there are fiber glass flag poles available that have sufficient height, but I don't know if they can support the weight of 100 feet of 3/4 in copper pipe and a 10-15 lb remotely tuned capacitor inside a weather-proof box.

Two other cautions for anyone modeling a J-pole with any NEC-2 based program:

1. Be sure to read the EZNEC manual section "Closely Spaced Wires" -- you'll find it in the index.
2. Run an Average Gain test. (See "Average Gain, Detecting source placement problems" in the manual index.) The small loop in closed-ended J-poles can be a problem for NEC-2. If the Average Gain test shows a problem, using the double precision calculating engine (available in EZNEC+) might help.

hi,

A large sheet of 6 mil clear plastic should be able to
cover the tower and the folded over section.

Place a container of DampRid on the rotor shelf
before you cover the tower with the plastic sheets.

Two layer of sheet should do the trick.

Drape the plastic 4 or 5 feet below the rotor,
no way for any water to get inside the rotor.

Tie it tiht with some good rope and your done.

The damp rid will absorb any moisture that it
trapped during the day from the hot sun
heating up the top of the 'rotor bag' you just made.

Or just take the rotor inside.

good luck with the repairs.

russ

Free space? As a data point, I pushed EZNEC to the limit on 40m
with a 9000 ft. dipole. Resonant feedpoint resistance at
7.152 is 390 ohms. Anti-resonant feedpoint resistance at 7.092
is 1980 ohms. It appears that EZNEC would converge to something
in between those two values for an infinite dipole in free space.
I ran into the segment limit at 66 wavelengths.

Note that those are not the feedpoint impedances. They are
based on the current maximum points which often occur
somewhere besides the feedpoint.

762. 802.11 antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-19 10:21:18 UTC
From: titus@ieee.org
Message-ID: <1127125278.923840.211310@z14g2000cwz.googlegroups.com>
Source record: 70460

Hello,

Can someone tell me what type of electical length does 802.11 antennas (lambda/2, lambda/4, etc) have? The 2.4GHz has 12.5cm wavelength but none of the rubber duck antennas that come with the wirless router have a length of 12.5cm, 6.25cm, or 3.125cm, etc.

I recently purchased a 9dBi antenna to replace the 2.2dBi stock rubber ducks. It also does not appear to measure in any n*lambda/4 lengths. What puzzles me is that an outdoor $200 antenna of 3 foot long and a $60 antenna of slightly less than 1 ft both have about the same gain.

And before the purchase I have tried to make a few higher gain antennas out of a wire coat hanger in n*lambda/4 lengths but they don't have much of an impact in signal strength. Why?

I did an antenna course years ago and remember the gain of a monopole is related to its radiation resistance, which is proportional to n*lambda/4 from what I can recall.

Thanks!

welcome to the foggy world of advertised antenna properties. i would guess that in the 802.11 stuff there is probably just as little control over quotes of antenna gains, measurement methods, etc as there is an amateur antennas... this is why for a long time the arrl refused to print antenna gain numbers.

Bob, do you know where to find the details of the charges being made
against Baxter in this case?

My memory isn't nearly as good as I wish it was, but if I remember
correctly from the ARRL Audio News and Newsline bulletins on the
subject, he's not being charged for the scheduling and duration of his
bulletins, but on the content of the bulletins and the interference
they're causing with ongoing communications. There were also some
problems with so-called "Felony Complaint Affidavits" that he was
issuing to anyone that disagreed with him or didn't get out of his way
when he wanted to start transmitting his bulletins.

If I'm wrong on this, someone please let me know.

```
| "Roy Lewallen" <w7el@eznec.com>
| wrote in message news:11irkp8rmnk0ta0@corp.supernews.com...
| [...]
| The Z of an
| infinite length antenna is indicated by locating the centers of the
| circles and noting that the center converges.
| [...]
| Roy Lewallen, W7EL

If we discuss here
the impedance referenced to the input (base) current
- and not to the maximum one - then
IMHO:

The quoted text above does not prove convergence.

The convergence must be independent
of the way the length goes to infinity.

The centers of whatever circles
may converge to a finite complex number
but their radii have to simultaneously converge to zero,
to have convergence.

But the limit for Z exists
if and only if
both the limits for R and X exist.
Therefore if the limit for R is dependent
on the way the length goes to infinity
then its limit does not exist.

A guess for either a non-existent limit for R
or an infinite one comes out from:
http://antennas.ee.duth.gr/ftp/visualantennas/thedipole/films/fu010100.zip
[850 KB]
If either of the above is true for R
then the corresponding is true for Z:

The limit for Z does not exist
or is (in general) the complex infinity.

But always and only for the
the impedance referenced to the input (base) current.

Sincerely,

pezSV7BAXdag
```

John,
Would you be able to provide additional support from the bottom of the loop
to ground?
That might relieve the situation. Could you have the feed at the bottom
rather than at the top and
could the box be supported?

If you could support from the bottom and use a heavy walled copper pipe
which would provide
substantial rigidity, the fiberglass might work.

I suspect that the neighbors are not going to be enthusiastic about the
loop.

Allison,

I have heard good things about the Ten Tec Transverter and figured it
was time to give it a try. I am a RTTY Junkie and noticed a six meter
RTTY spot yesterday. The 1208 should be here on Tuesday.

Nowhere in The Bible does it say anything about a man finding
it difficult to go through the eye of the needle. The "eye of
the needle" gate was designed to allow men through, even rich
ones, and keep camels out. The difficult thing for men was to
enter the Kingdom of God, not get through the "eye of the
needle" gate.

Thanks, Ed, for your comments. Yes, If I have a supporting pole in the lawn, there is no reason why I couldn't also have a support directly below the loop. The loop would be in the shape of an octagon, it would be fed through either a 1/5 size coupling loop or a gamma match at the center of the bottom side, and the series resonating tuning capacitor would be inserted at the center of the top side.

The 3/4 inch copper pipe would be the same type that is used inside houses and is quite rigid. I can not seem to find, by Goggling, the weight of copper pipe. By going to the local Lowe's store and hefting a 10 feet length of pipe, I estimate the weight of 10 feet of pipe as being somewhere in the range of 1-3 lb.

> or is (in general) the complex infinity.

As the length of a dipole is increased, for the same
power input, more energy is radiated during the first
transcient cycle and less is available for reflection
from the ends of the dipole. Reflected energy is what
is causing the feedpoint impedance to change. As the
length of the dipole is incrementally increased, the
magnitude of the reflected energy is incrementally
decreased. I believe Balanis alludes to this characteristic
of standing-wave antennas.

The feedpoint impedance is Zfp = (Vfor+Vref)/(Ifor+Iref)
using phasor addition.

The limit of that equation as Vref and Iref go to zero
is Vfor/Ifor. That's what happens for an infinitely
long dipole. That's also what happens during the transient
phase of a finite dipole. Thus, Vfor/Ifor can be thought
of as the characteristic impedance of the dipole. Seems
to me, Vfor/Ifor could actually be measured during the
transient phase of a long finite dipole. Will a TDR
report the ratio of V/I for an RF pulse?

Cecil, W5DXP wrote:
"Note that those are not the feedpoint impedances.".

Well, the imprdance I qupted was the radiation resistance, which is the voltage to current ratio of an antenna at the maximum current point in the antenna. I was just too lazy to post the complete Table given by Bailey.

Only when the order of resonance in a center-fed dipole is odd, 1st, 3rd, 5th, etc, is the feedpoint resistance the same as the radiation resistance. In odd-ordered resonances, the antenna feedpoint resistance is te same as the radiation resistance. In odd-orfered resonances, the antenna feedpoint is at s current loop.

In even-ordered resonances, the value of the feedpoint resistance is equal to the feedpoint impedance squared, divided by the radiation resistance value. Bailey has worked it all out for us.

Best regards, Richard Harrison, KB5WZI

My Lowe's store sells two kinds of copper pipe. The less costly one is harder, lighter and thinner. I began my antenna experients with the huskier stuff and after it bent, replaced it with the thin material, which is holding up OK so far.

The thinner material seems to have about the same weight per foot as aluminum. I'm using copper instead of aluminum because it is easier to make good electrical connections between the pieces.

Do you mean that
since the length is infinite
there is no reflected wave?
But then here it is,
once again,
one of the most controversial issues...

Well,
I think we are in the front of a case in which
the limit depends on the way we approach it.
Every logical way to approach a limit is permissible.
And these ways are infinite in number of course.
```

But the convergence is too demanding:
"She" wants all these limits to be equal.
If just two of them are unequal
the convergence simply does not exist.
Mathematically this is not a rare case,
they say.

Sincerely,

pezSV7BAXdag

The Lowe's store here was stocking Type L Hard 3/4" copper pipe 10' long for $10. However, they only had one item in stock. I am guessing the demand for construction material due to the recent hurricane will cause shortages and higher prices.

==========

The characteristic impedance of an infinitely long wire is Zo.

If we cut the line and measure between the two ends we obtain an input impedance of twice Zo. Which is the answer to our problem.

Zo is a function of wavelength, conductor diameter and conductor resistance R where R includes the uniformly distributed radiation resistance. On a high Zo line the radiation resistance is small compared with Zo and the only effect of the radiation resistance is to give Zo a small negative angle. Which when estimating Zo can be ignored. (It is conductor resistance which at HF gives Zo of ALL lines a very small negative angle).

In the problem posed, the current is also uniformly distributed along the low-loss line and radiation resistance is not the value we are familiar with and what we might do with it.

And so we get approximately -

Rin = 120 * (Ln(Wavelength / 2 / d) - 1)

At a wavelength of 2 metres and a conductor diameter of 10mm the input resistance = 433 ohms.

I cannot guarantee the above formula to be correct. But is it low enough for you? ;o)

Mr Wu calculates radiation resistance which is not the same as input impedance unless correctly referenced. It is usual in technical papers to calculate Radres at one end of the antenna. Or it may be the

distributed value. I havn't the time to find and study the full text.
From past experience, with me, it usually ends up as a wild goose
chase.

Reg.

> one of the most controversial issues...

Yep, it's my digital logic in action. :-) If there's no end,
then there cannot be reflections from the ends. And please
note that I am not saying that the characteristic impedance
of a dipole is constant all up and down the line. I'm only
concerned about the apparent characteristic impedance at
the feedpoint, i.e. Vfor/Ifor.

Consider an open circuit transmission line. At 1/4WL, it
exhibits a very low impedance. At 1/2WL it exhibits a very
high impedance. As the transmission line length is increased
to infinity, because of losses, the "stub" impedance will spiral
into the Z0 characteristic impedance point. A similar concept
should apply to a dipole.

Reg, in the real world, an antenna has radiation losses so
the current decays along its length. Is there any formula
that includes an attenuation factor for a traveling wave
antenna? It would be akin to the attenuation factor for
a transmission line but presumably higher.

I have estimated that, for a 1/2WL dipole, the reflected
voltage and current have dropped by approximately 10% below
the forward voltage and current during the round trip to the
ends of the antenna and back.

One point: Isn't the input impedance of a dipole normally specified at
a wavelength equal to twice the electrical length of the antenna? As
far as I know, dipoles have infinite DC resistance at zero Hertz. ;-)

This assumption is correct only when the transmission line conductors
are closely spaced. That isn't at all true for the halves of a dipole.

I can't see how it can possibly be correct. Unless I'm mistaken, you've
completely ignored the effect of radiation in calculating the radiation
resistance. It sure makes the calculation a lot simpler, though!

> chase.

It depends on the author. Kraus uses feedpoint resistance and radiation
resistance interchangeably when loss is assumed to be zero. It's

traditional in AM broadcasting to give radiation resistance referred to a current maximum. The conclusion is that radiation resistance can be referred to any point along an antenna you wish, which means that it's essential to state what point you're using as a reference.

No, you can calculate or specify the input impedance of a dipole at any frequency. As frequency approaches zero, a dipole's input resistance approaches zero and its reactance approaches minus inifnity. That is, it looks like a capacitor, and the capacitive reactance gets larger as the frequency gets lower. Which is just what you'd expect from a couple of electrically very short wires having no DC connection.

==============================

Yes, I know. Just insert "approximately" before "uniformly"

On a long terminated non-resonant line I guess the current falls off
crudely exponentially at a rate of about 1 dB per wavelength.

The situation is similar to that very long, low, terminated antenna
wire whose name I can't remember. And whose input resistance at LF is
about 550 ohms. Putting two of them back-to-back gives an input
resistance of twice that = 1100 ohms. Which indicates the answer to
our infinitely long dipole problem.

The TT I had had a very hot receiver. I had the marage amplifier with the gasfet preamp and when I turned on the preamp I could not tell any differance in the weak signals. The S-meter came up but the noise came up with the signal. I could get the same effect in the audio just by turning up the volume on the receiver.
On transmitt, 10 watts or so is still 10 watts. Just a little too low for me on 6 meters. With many of the newer rigs having 100 watts on 6 I think that is the power level to shoot for.

For what is it , the transverter does a very fine job.

Sure. 42. It might not be better, but it's just as good. Formulas can be made very simple if you simply ignore any inconvenient facts. Like radiation from an antenna.

Don't be silly. I didn't ignore radiation resistance. I said it was
small enough in comparison with Zo, as an approximation, to forget
about.

And remember Lord Kelvin.

> n*lambda/4 from what I can recall.
>
> Thanks!

t
You are correct, the radiation resistance partly depends on, or partly governs, the dimensions (depending on how you look at it). The size (length) of the antenna depends not only on the diameter of the wire, but on the surrounding material too. An antenna can be made shorter than what you would expect by simply increasing the permittivity (or dielectric constant) of the material around it. My guess would be that the antenna is coated with a high permittivity material which (in the material) makes the wavelength of any frequency appear shorter than it actually is. So the antenna only actually has to be as long as the quarter wavelength in the dielectric.

Another possibility would be to introduce a reactance (inductance or capacitance [I can't remember which at the moment]) to shorten the electrical length of the antnna, thereby, once again, only requiring a shorter than expected antenna length.

As far as your tests go, I can't really comment on why you don't see a change. But... If you'll recall from your antenna course, a lambda/2 dipole has a figure 8 pattern when looked at from the side (E plane). If you increase the length of the dipole (or monopole with a ground) you are effectively creating an antenna array and you get interference

from each element (each section of lambda/2). Your figure 8 with a low gain broad main beam begins to look like a flower with thin petals. Each petal (lobe) has higher gain but a narrower beamwidth. You may be getting multipath (a type of interference) due to the extra lobes or you simply may be looking from an undesireable angle. Perhaps you could try moving your non homebrew antenna station in the E plane of your antenna and see if the signal strength changes.

I hope this sheds some light!

Dario

That would be true for an electrical dipole but we are obviously
talking about physical poles here, i.e. two infinite conductive
fishing poles. :-)

Seems to me if we assume 1 dB per wavelength for both current
and voltage and knowing the feedpoint impedance of a one WL
dipole, we could calculate the characteristic impedance of
the antenna at the feedpoint.

Seems to me it would be essentially the same calculation as
for a 1/2WL open-circuit stub where the transmission line has
losses of 1 dB per wavelength and we measure a stub impedance
of 5000 ohms. We could calculate the Z0 of the stub.

Couldn't we use a TDR to measure the loss in an open-ended
1/2WL piece of wire?

Hi Dario,

Thanks for the information on the permittivity factor allowing a shorter antenna due to a shorter wavelength, and for pointing out the array part for a longer monopole. I actually did quite a bit of analysis on arrays in multiple dimensions but never thought a longer antenna element would be equivalent to stacking up monopoles. So thanks for pointing that out.

But part of the question remains, I guess then is how would be possible to increase gain of a monopole without going over lambda/2, while maintaining the dounut shape radiation pattern of a monopole.

Also, out of curiosity, why would any one wants to pay $200 for a 3 ft long antenna vs $60 for a less than 1 ft long antenna of the same gain, only because the $200 is an outdoor one?

| ------------------------------------------------------------

A
I hope you will excuse me the next example.

Let

f = Sin[x]

I choose:

x = 2*k*pi

and k goes to infinity one by one: 0, 1, 2, ...

Definitely then I found correctly f(oo) = 0.

Cecil chooses:

x = 2*k*pi + pi/2

and k goes to infinity one by one,
as before.

Definitely he founds correctly f(oo) = +1

Lord Kelvin chose:

x = 2*k*pi - pi/2

and k went to infinity one by one,
as above.

Definitely he founded correctly f(oo) = -1

All of us
we are correct in all steps,
but the value
```

f(oo)

does not exist as a single one.
In fact f(oo) takes every value between -1 and +1.

f(oo) definitely depends
on the way in which each one of us
went to infinity.

IMHO:
this is the kind of behavior of Zinp.

B
But in addition to that there is one more to say:

Zinp is a result of
the order in which we consider the limits
for the wire radius and the length to wavelength ratio.

If
a is the wire radius and
L/wl is the ratio of length to wavelength
then
I can imagine five cases:

1
First the a is going to zero,
a formula is produced for Zinp,
then the L/wl is going to infinity
and a number may or may not be the result for Zinp.

2
First the L/wl is going to infinity
a formula is produced for Zinp,
then the a is going to zero
and a number may or may not be the result for Zinp.

3
Simultaneously,
both
the L/wl is going to infinity
and
the a is going to zero,
and a number may or may not be the result for Zinp.

4
We keep a constant value for L/wl,
then a is going to zero
and a number may or may not be the result for Zinp.

5
We keep a constant value for a,
then L/wl is going to infinity
and a number may or may not be the result for Zinp.

[On the occasion I have to confess that the movie at
[http://antennas.ee.duth.gr/ftp/visualantennas/thedipole/films/fu010100.zip
[850 KB
[belongs to the last case.

For a possible conclusion
let me mention a remarkable note from a Mathematical book:

"The biggest source of erroneous conclusions
have to do with the order we consider the limits"

(and which order we tend then to forget ...)

Sincerely,

pezSV7BAXdag

804. Edmund Laport "Radio Antenna Engineering" now in paperback edition

Back in May, I announced the availability of an electronic (PDF) edition of Edmund Laport's 1952 text "Radio Antenna Engineering", which I'd created by scanning a copy of the book after I confirmed that the original copyright had expired. The reaction to this has been quite satisfying - it's been downloaded over 200 times via my BitTorrent server, and at least as much more from one or another HTTP server.

A few weeks ago, I received an excellent suggestion from Ed KI4AGL. He proposed that I upload the PDF to LuLu.com, a "publish and print on demand" company, so that people who wanted a hardcopy of this book could purchase one conveniently.

I hadn't heard of LuLu, so I checked them out, and was impressed by what I saw. It turned out to be quite easy to set up an account, upload a slightly-tweaked version of the book's PDF, create a cover for it, and make it available to purchasers. Ed ordered one, and wrote me yesterday to say that it has arrived and that it looks good - the text and pictures all came out clearly. LuLu describes their product as being "bookstore-quality paperbacks" and from Ed's report it sounds like that's a fair description.

As published through LuLu, "Radio Antenna Engineering" is a 6-by-9-inch softcover, printed on 60-pound paper stock, with a glued-edge "perfect binding". It's what's usually called a "trade paperback" edition, the same size as the original hardcover edition, and has all of the text and drawings and photographs. The large foldout map of the continental United States, with diagrams of the coverage patterns of certain MF broadcast stations, has been reduced down to fit on a single 6-by-9 page.

The price for the book is set by LuLu - they charge by the page and add a flat fee for the binding. I published it using LuLu's "no royalty, no commission" service, which they've set up specifically to encourage people to keep obscure material in print. Postage is additional, depending on how you choose to have it shipped. With basic (media-mail) postal delivery in the U.S., the book comes to a bit less than $20.

You can order it from: http://www.lulu.com/content/159004

I've added this information and link to my page at http://snulbug.mtview.ca.us/books/RadioAntennaEngineering/ on which you can find the BitTorrent download files, and links to an HTTP server which has the PDFs available.

Even with your disbelief, I'll still pray for you.

There are two common anecdotes. One in Christianity, the other in Islam.

1] Work like everything depends on you. Pray like everything depends on God!

2] Trust Allah, but tie your camel.

Here is a message from a Baptist [Christian] Pastor about 10 years ago.

"Man does his part; God does His part.
Man does the sinning; God does the saving."

May God increase your faith.

808. Telonic VSWr kit "Rho_tector" - anyone used one ?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-20 10:51:09 UTC
From: David <groups@orbitcoms.com>
Message-ID: <xQRXe.589$0E5.486@news-server.bigpond.net.au>
Source record: 70405

Hi,

I have a Telonic VSWR kit (Model TRB-2) tha is supposed to be good to
2.5GHz. It has 0.5W rating stamped on it , Z1, Z2 , RF in and Detector out.

It came wikth 1:1 and 2 x 2:1 Precision terminators.

I would like to measure VSWR of antennae at 915 MHz using a RF Sig. Gen,
the VSWR kit and a scope. I have a 1GHz spc analyzer also if required.

1. Can I drive this properly with the +13dBm max. from the Sig. Gen and
get reasonable results ?

2. If so, what would be a good setup and test method.

Thanks in advance for any help.

Regards

David

Dave,

I downloaded the free copy of this and looked at it. It is a very fine piece of reproduction work on your part. The care you took to line everything up correctly, as well as the quality of the scans, have resulted in a reproduction that is almost as good as new. I intend to peruse it a little, and then perhaps purchase a professionally bound copy from the LuLu service you identiified.

Thanks again for your hard work and a great job!

I have a 1/2 wave - end fed whip antenna that has been designed for operation on 915 MHz.

A Signal Generator is attached to a VSWR detector. The reference port is 50 Ohms. The antenna is connected to Z2 port and the detector output to an oscilloscope.

I have calibrated the output for 50 Ohms and noted the 2:1 VSWR voltage when using a 2:1 precision ref at Z2 in place of the antenna.

I have a Spectrum analyzer with short wire as a pickup to observe radiation from antenna (I image 1/2 the trouble is here ?)

When I sweep manually across say 800 MHz to 1GHz the VSWR gets worse when the radiated power increases and visa versa.

When I then plug in a commercial antenna the VSWR does the same thing EXCEPT when it is in the region it is resonant, the VSWR improves as the level rises, at all other points the VSWR goes down as radiated power increases.

Is there something silly going on here or is this what should happen.
This is the first time I have attempted to measure an antenna so would appreciate any help.
I notice the peaks at a reasonably fixed period (816,879,933,993,1.051G), can I learn something about the antenna from how apart these peaks ?

Thanks in advance,

Cost to manufacture/distribute is often the calculation starting point when determining final price..

Prices tend to be set at whatever the market will bear.... Also note that those with flashy paint jobs and go-fast stripes will always cost more! <grin>

Antennas designed/built long ago may have to amortise higher design costs. Then again more sales over the years should have bought the price down.

Quality? Longevity? Gain should not be the sole method for making a choice of what antenna to buy. I personally would also look at sidelobe performance (for reduction of possible interference). One also has to calculate the path requirements and signal margins to do the job properly. Allowing for cable loss is another biggy. Many big spread spectrum suppliers (eg Cisco) have a spreadsheet you can download for calculating the link budget for an LOS path.

Re increasing the gain w/out and incerase in size, generally not. If you load the elements in such a way that they are smaller to make use of phasing (eg a collinear) then losses are introduced as well as the aperture getting smaller. My opinion is that you'd have better directivity but no/little increase of gain in the intended direction. The donut would be flatter by the way.

Would you care to explain your exact requirements? Like are you trying for point to point links or just a larger hot spot coverage. They have diferent antenna requirments.

Cheers Bob W5/VK2YQA

If the wire is significantly less than a wavelength on the spectrum
analyzer it shouldn't cause effects that are _too_ weird, and is
probably better than hanging an unknown sorta-tuned antenna on the thing.

You mentioned the Magic Flame War Word when you mentioned VSWR. The
relationship between VSWR, amplifier performance and antenna performance
is complex. I'll get behind this here bunker and say that VSWR
measurements are useful things if you know the effects, and if you're
using components that are designed for 1:1 VSWR at some design impedance
that's what you should do. Beyond that a given amplifier may not have
it's peak power output at 1:1 VSWR, and a given antenna may not have
it's peak effectiveness at 1:1 VSWR, unless the amplifier and antenna
are specifically designed for that. Try to ignore the side threads that

this paragraph will generate -- those folks all voted for either Nader or LaRouch in the last election.

Did you pay attention to the amplifier power output when you were doing your VSWR sweep? Did you try moving the spectrum analyzer pickup around? An amplifier that's designed for a 50 ohm output and run into a different impedance may indeed generate more power, at least until the finals overheat. It may be that the amplifier you're using happens to generate more power into the off-tune load that the antenna presents - or - that the antenna radiates more efficiently in the direction of your pickup.

Last time I inquired about this antenna I was told it wasn't
an end-fed but instead was a center-fed sleeve antenna. So
which is it? (Anti)resonance on a bona fide end-fed 1/2WL
antenna is pretty hard to nail down but it doesn't much matter.
One just usually searches for a 50 ohm tap on a coil.

Source record: 70415

A half-wave end-fed wire, fed against a ground plane or similar counterpoise, will show a high impedance at (and near) resonance. If the antenna is fed through some length of line from the "VSWR detector," the impedance presented to the detector will be modified by that length of line; a 1000 ohm antenna might reflect 3 ohms through the line. But why would you expect a drop in indicated VSWR at resonance? -- When you say "when the radiated power increases," are you talking about increased field strength as measured by the spectrum analyzer, with a constant output setting from the generator? How far away is the spectrum analyzer antenna, in wavelengths, from the antenna you are trying to measure?

If, as Cecil suspects, the antenna is really a center-fed half-wave, what have you done to decouple the feedline from the antenna? If the feedline comes coaxially out the end of the antenna, it may well be that the feedline is very poorly decoupled.

Cheers,
Tom

Hi Jim,

Certainly a trove of complexity. Keeping to the tenor of your choice:
"I have not had a moment's peace or happiness in respect to
electromagnetic theory since November 28, 1846. All this time I
have been liable to fits of ether dipsomania, kept away at
intervals only by rigorous abstention from thought on the
subject."

I sippose that California varietals were not available as an
alternative to ether. Oh how we can celebrate the modern march of
progress by viewing the problems of electromagnetic theory through the
bottom of a wine glass. Such libation allows one to simultaneously to
offer solutions and to observe that "rigorous abstention from
thought." Lord Kelvinator would be proud.

"Radio has no future."

Hi Jim,

Almost any lesson can be drawn from the hazard of quote choices:

"The wireless telegraphy is one of the most wonderful inventions
the world has ever seen."

One has to allow that he was either a world class loon, or had the
ability to change his mind.

No doubt the latter characteristic prevails, but this is hardly the
forum for its celebration.

Thanx for the link to such a trove.

David,

Judging from your comment above, it appears that the VSWR peaks are happening at a very periodic spacing of about 60MHz. This would imply to me that you're analyzing the antenna by looking into a feedline that is 1/4 wavelength long at 60 MHz. This would be about 49 inches times the velocity factor of the coax. Thus I'd estimate that your feedline is in the mid 30" range. Is this the case?

Hi there,

I want to install a long wire antenna to my Sony ICF-SW7600GR, so I'm wondering whether it will significantly improve reception of already available broadcasts as well as getting new, farther, emissions.

How that long wire antenna should be made? I mean length, kind of wire, ...

I'm quite naive in the shortwave listening world, thus any kind of help would be very appreciated!

The Rhotector which I know is a Wheatstone bridge. It has a built-in
detector. The output is DC. You don't need a spectrum analyser. You can
use a multimeter. I used it with a sweep generator which had a maximum
output of about 56dBmV (about 8dBm).

The easiest way of using it is to insert a switched attenuator between
the generator and the RF input port. Connect the 1:1 load to Z1 or Z2
(the 'reference' port), and a 2:1 to the other (the 'unknown' port).
This represents an RLR of 10dB.
Set as much attenuation in which is consistent with getting a sensible
level of DC out (say, 20dB). Note the reading.

Remove the 2:1 load, and connect the antenna. Re-set the attenuator to
give the same DC reading. Note the attenuator setting.

The RLR of the antenna is simply 10dB + or - the difference in the
attenuator readings.

There is a small amount of error because the loading on the generator is
affected by the load on the 'unknown' port (unless the generator has
zero output impedance, which it won't have). There ways of reducing

this, but it isn't worth it. Your answer will be good enough for most purposes.

I'll send a diagram if you need one.

Cheers,
Ian.

Source record: 70423

Does the antenna you bought show a squashed donut shape for its pattern? Does it show a pattern at all? Telling you 9dBi doesn't say very much on how the antenna performs. It may be (unlikely though) that the 9dBi is only good through a few degrees of space (a pencil beam pattern). Knowing something about antennas obviously helps.

You posed a good question. It made me do a little research and I came up with the following. As you may also recall, if you space your elements in a an array lambda/2 apart. You get higher gain in the broadside direction. Say you stacked many monopoles (end to end) and made sure their phase centers (feed points in many cases) were lambda/2 apart the donut shape would be slightly preserved, squashing it down to a flatter donut, thereby increasing the gain. (Higher gain equates to narrower beamwidth). You would ultimately end up with a donut with ripples as you moved from the "hole" to the circumference of the donut. The points farthest away from the center would be the 9dBi gain. And as you would expect, you would only get that 9 dBi through a few degrees from the center of the antenna. The tricky part in this is feeding the many monopoles inside the plastic shaft in which your antenna array is encased. You want to be able to feed the monopoles without having your feed network radiate and throw off your desired pattern. This is where smarter people than I come in...

As for your question on the price... As Bob Bob said, gain isn't the only characteristic antennas have. The price difference could represent a differene in phase linearity from one point on the pattern to another. The matching network, beamwidth, bandwidth, side lobe levels, and a few others also make one antenna more desirable than others.

Regards,

Dario

827. Re: How do you find antenna resonance

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-20 23:42:24 UTC
From: David <groups@orbitcoms.com>
Message-ID: <A71Ye.987$0E5.559@news-server.bigpond.net.au>
Source record: 70424

Sorry about my description of the antenna. I still have not yet come to grips with the terms of reference. I called it end fed because the coax enters at the bottom but I have been advised it is actually a centre fed dipole.

The decoupling is via a 1/4 wave sleeve that provides high impedance for RF returning along outer coax and also as the second 1/2 of the dipole.

The level I noted is the signal strength seen on a spectrum analyzer (80mm wire at end of 1m cable) - this may be the 30" section that is producing the 60MHz dips. I also noticed the wavelength of this pickup wire is close to 1/4 wave at frequency of interest.

Would I be better to put a directional coupler in line with the Signal Generator output and sniff off to spec analyzer and look at dips in signal strength as indication of radiation occurring ? (I would like to see what the radiated power is doing at the same time as the VSWR is all over the place and hard to see what is happening when looking at that only). If I can do away with the wire pickup on the spectrum analyzer I can at least remove the effects of this being super imposed on the results.

The commercial antenna I am comparing against does have a peak radiated power at min. VSWR at frequency of interest and my antenna does not.

The style of antenna is the same (1/4 wave shunt sleeve and 1/4 wave radiating element).

Thanks for any more help.

Regards

David

Cecil

I have been in contact with David. I gave him sketches for building a centerfed 1/2 wave dipole with the coax feed line running inside one half of the dipole. I am sure he has constructed an antenna like that, center fed half wave dipole.

Jerry

Sounds reasonable, Reg. To put it for simple people like me, it would mean it's a transmission line of diameter x with an infinite diameter shield. Then we feed 2 of them, balanced, colinear, and that's our R sub r.

Did I misunderstand?

==========
Tom,

Twas not I who posed the original "input impedance of an infinitely long dipole" question.

The radiation resistance does not enter very much into the solution. But in any case the radiation resistance is not the one we are accustomed to because the current distribution along the wire is not of sinewaveform but decays rather slowly exponentially.

I've just remembered the name of the real antenna which best fits the problem. It is the terminated Beverage which is just a very long horizontal wire some distance above ground.

The Zo of the Beverage is 60 * Ln(4 * Height / d) ohms, where d is wire diameter. When terminated its input resistance at LF is Zo (see the Bible, the ARRL Antenna Book). A typical value of Zo is 550 ohms.

Note that radiation resistance does not enter the formula although it cannot be denied radiation does occur. The formula is a close approximation which serves present purposes.

Putting two Beverages back-to-back to make a dipole we get an input impedance of 1100 ohms. The infinite dipole is in the same high impedance ballpark.

To calculate Zo of an isolated infinite dipole we shall have to change dimensions Height above ground disappears and is replaced by wavelength (or frequency).

Zo = 60 * (Ln(Wavelength / 2 / d) - 1) ohms, approximately.

A more exact formula involves inverse hyperbolic functions and wavelength, height, wire length, and wire diameter, but nobody ever uses it. You won't find it in Terman.

On the favourite American 40-meter band with a 14 AWG infinitely long wire Zo = 505 ohms.

Which makes the dipole input impedance = 1010 ohms but a nice, round 1000 ohms is near enough for me.

Your 'infinite shield' is a fair description for the return path but the end-effect is fairly large. I prefer 'the rest of the Universe'. But the nearest point is still the Earth's surface.

I leave the people, who attempted to use Smith Charts and Eznec to solve the interesting problem, to fathom out where they (or the charts or Eznec) went wrong.

Reg.

Christian Charity is a point scoring exercise with God. It is done for
selfish reasons, to make sure you are noticed by God and he lets you in.

By the way, you can easily, convert the 4SqTL.EZ file into Nec2 or Nec4 format (to do some further comparisons) by opening it in 4nec2. It should be automatically converted, including feed-line system.

Success,
Arie.

Hi David,

You wrote, "The decoupling is via a 1/4 wave sleeve that provides high impedance for
RF returning along outer coax and also as the second 1/2 of the dipole. "

EXACTLY how is this built? The details of construction make a BIG difference in performance! (There's a lot of BAD info about it out there...)

It's not a bad idea to ALSO put some additional decoupling further down the feedline.

If your spectrum analyzer/field strength meter is far enough away from the antenna you are testing, then it should provide a reasonable indication of relative antenna radiation performance. The SWR indication, if properly calibrated and given that you are apparently exciting the antenna with a source whose output impedance matches your feedline, should also be a good indication of power actually absorbed by the antenna. That is, lowest SWR represents maximum power absorbed by the antenna. Presumably that power is being radiated as RF, mostly, and not dissipated as heat. But where the RF radiation goes depends on the pattern of currents excited on the conductors that compose the antenna, and nearby conductors as well (such as the feedline). What you probably want is standard resonant half-wave dipole currents on your vertical dipole, and no (very little) antenna current on the feedline and on support structures. By the way, whether the antenna is resonant or not is of little real importance, so long as you can efficiently feed power to it and the antenna currents are in the right places and not the wrong places. But it happens that with your antenna, if things are working properly (properly decoupled feedline, etc), you probably will see lowest SWR at half-wave resonance. If you have no other matching going on, the lowest SWR will probably be about 1.5:1 with 50 ohm feedline. You could add parts to get a better match if you wished.

And as you can probably tell from all that, I'm suspecting that your decoupling sleeve, with associated dielectrics in that area, probably isn't doing a very good job...

Also...Joe noted that your coax feedline may well be a length that accounts for the SWR peaks and valleys. (I think it may be about twice as long as Joe wrote...but same idea.) Do you see the peaks and valleys when you terminate the line in the precision 2:1 load? If you do NOT, then it's a further indication that the feedline has antenna

currents on it, because the flat 2:1 is an indication that your transmission line is matched to the calibration impedance of the SWR bridge, and if that's the case, the SWR bridge should be giving at reasonably accurate estimate of the actual line SWR. If you DO see the SWR ripples vs frequency with just the precision load, either the load isn't "flat" or the line is not the same impedance as the SWR bridge is calibrated to, and the differing impedances is by far the most probable explanation if the line length is right.

Cheers,
Tom

I hardly consider myself a fanatic, and am extremely unlike to "hammer"
anyone over religion, or lack there of.

Some of the most fanatical are those members of the religion of atheism.

These folks find it threatening that someone may have a set of beliefs, and
feel the only recourse is to attack those beliefs. Makes one wonder if they
find it necessary to stand in department store lines, demanding that little
children give up the idea of Santa Claus, which they find equally
believable.

I personally don't care what anyone's belief set is. I do find it abhorrent
that some are more active for atheism , than a Jehovah Witness beating on
the door selling salvation.

My feeling is that most are simply crying out for attention, and know the
religion button is a simple one to push.

They have only recently decoded the chimp's DNA genome.
The new figures seem to be 96% identical, 98.5% very similar.

Fred brings up an interesting point. Atheism IS a RELIGION!!

I define RELIGION as a set of beliefs that influence behavior.

Merriam-Webster defines RELIGION in a similar fashion [Note #2 and 4]:

"Main Entry: reï¿½liï¿½gion
Pronunciation: ri-'li-j&n
Function: noun

Etymology: Middle English religioun, from Latin religion-, religio
supernatural constraint, sanction, religious practice, perhaps from
religare to restrain, tie back -- more at RELY

1 a : the state of a religious <a nun in her 20th year of religion>
b (1) : the service and worship of God or the supernatural
(2) : commitment or devotion to religious faith or observance

2 : a personal set or institutionalized system of religious attitudes,
beliefs, and practices

3 archaic : scrupulous conformity : CONSCIENTIOUSNESS

4 : a cause, principle, or system of beliefs held to with ardor and faith"

If we accept this definition of "religion" as a system of beliefs that contains unprovable statements taken only on faith, then Kurt Godel taught us that mathematics is not only a religion, it is the only religion that can prove itself to be one.

Message-ID: <oylYe.9306$0E5.5010@news-server.bigpond.net.au>
Source record: 70353

Tom,

Thanks for the information. The inner coax is the smaller RG174 coax.
The sleeve is made of earth braid pulled from RG58 cable. The dielectric
between the sleeve and inner cable is therefore the outer sheath of the
RG174 cable (Not sure what this is, the RG174 I have is Teflon inner
dielectric and stranded conductor. The utter sheath is a very strong
heat resistant material - I therefore have no ideal of the dielectric
constant to calculate Vp for correct electrical length). If I use a
copper tube and strip off the sheath from the inner coax, I can
calculate correct length as it will have an air dielectric.

Do you know where everyone is getting the dielectric constants for
various materials ? I noted people using small metal tubes as sleeves
and quoting these magic numbers even for copper tubes of certain diameters.

From my discussion with Telonic, they say the Rho_Tector was designed
as an in-house tool for measuring inputs of amps and filters. They
suggest SWR meter would probably be best for antenna adjustments.
Do you happen to know where I might find details for a low power SWR
meter for 915 MHz ? I need one that will operate with only 20mW applied
power. The only SWR meter I have has min. FSD of 3W

Thanks

Regards

David

Wow. I have faith that if I fall off the rim of the Grand Canyon, or
any great height, that I will most likely bite the big on upon landing.
Therefore I do not engage in risky behavior such as spinning around
until I get dizzy when I am near the edge of long drops.

I believe that I will bite the big one if I fall hundreds or thousands of feet. My belief most definitely influences my behavior.

So Have I come up with some new sort of religion here?

And I truly see you reading a lot more into this than the definition provides

Hans, the Atheism as a religion is just a reserve argument that the CC Fundies are holding in their hands, so that they can claim that Evolution is a (atheistic) belief, and therefore a religion, which leads to the argument that they have every right to force their religious beliefs on us, since the "religion" of evolution has been forced on the nations children for so long.

Hi,

Some of you, hopefully many of you, may be aware of the existence of the "Amateur Radio Course" project which provides a number on-line and downloadable tutorials for the various UK amateur radio examinations.

Due to the sudden, unexpected and unexplained withdrawal of support by the company who up to now have very kindly hosted our web-site free of charge, and their even more unexpected failure to communicate with me regarding how we might transfer or redirect the URL which they registered for us but now will not let us use, our site is no longer available to the clubs and individuals who benefited from it.

Can you therefore help us and please publicise as widely as possible the following information.

The "Amateur Radio Course" which was located at www.ukradioamateur.org is now relocated at www.radioamateur.co.uk

There may be a number of functions that are not working due to the sudden move, but they will be fixed within the next few days.

It remains, as always, a non-profit making activity sponsored and supported entirely by the group of individuals who give up their time and resources free of charge to support and promote interest in the hobby.

I apologise for posting this message in so many newsgroups, but I need the new URL to be publicised as rapidly as possible.

Many thanks to you for your help, best wishes and 73's

Chris

Hi Hans,

Godel actually taught us that any system of belief, by its own rules
of consistency must include the statement that

1 + 1 = 3

Technologists would find that quite difficult to live with, some of
the religious (if not in that same crew) would also find it difficult.
Then there are those who would simply accept it on faith.

I would expect the outer is a Teflon or Teflon-like material, with probably low loss and fairly low relative dielectric constant, but it's still going to require that you shorten that lower section quite a bit to get the quarter-wave stub to reflect a high impedance. In addition, the dielectric between the outer of the coax and the inner of the sleeve is pretty thin, and the impedance of the resulting coaxial arrangement is pretty low. That means that it won't ever reflect a very high impedance. You can use a tapered sleeve that bells out at the bottom, to good effect. That will also lower the feedpoint impedance and match better to 50 ohms. Think: ground plane with drooping radials. But you can also wind the coax just below the antenna into a small coil (I'd make the axis of the coil coincide with the axis of the antenna) that's self-resonant near your operating frequency, and it will very effectively choke off antenna current (current on the outside of the coax) at that point. Put one such coil an inch or so below the bottom of the sleeve, and another about a quarter wave further down the line.

SWR meter: Get RFSim99--do a Google search for it. Build a coupler, per tools>>design>>coupler. I'd suggest a microstrip version, if you can make a little PC board reasonably accurately. Design it for 50 ohms. Terminate each coupled port in 50 ohms (e.g. 49.9 ohm 0805 SMT part). Using vanishingly short leads, connect a simple diode detector to each of those two loads. Use a calibrated attenuator to calibrate at least the relative response of those detectors. Use those two outputs to calculate SWR. You can read the diode detector outputs with a DVM that has good resolution (10uV sensitivity preferred; 1uV is even better). I'd recommend about a 20dB coupler for the power level you're using, though even a 30dB coupler would work. Try terminating the through line in a 49.9 ohm (or a parallel pair of 100 ohm) 0805 parts to check that you see essentially no reflected, and try a 100 ohm load and a 25 ohm load to check that you get the expected reflected. -- To have the coupling right according to the RFSim99 directions, it needs to be 1/4 wave long, but it's a pretty broad peak. Coupling drops to zero at 1/2 wave, and at DC. So you could make one for 900MHz, and it would work OK at 450MHz, you'd just get lower coupling. The ratio for SWR would still be OK. The 450MHz version on FR4 board (fiberglass-epoxy) would be roughly four inches long, if my mental arithmetic is right, and half that for 900MHz.

Cheers,
Tom

Tom,

Thanks for the suggestion. I have used RFsim and come up with dimensions for a 915 MHz version.
I would like to put a coupling strip each side of the centre to pick up forward and reverse power at the same time. The description in RFsim don't mention this - Do you know if I need to make any alterations in dimensions to accommodate this or should I have a second 1/4 in series with another coupler that picks up reverse power ?

I would like to use the AD8302 Gain/Phase device to measure the incident and reflected voltages. This thing will has an input range of -60dBm to 0dBm which will be great if I feed the directional coupler with 0dBm and the coupling is -20dB. It provides measurement for +/- 30dB and Phase orange over 180 degrees. It also will operate to 2.7GHz so should be ok for the 915Mhz.

I thought I would make this gain/phase detector in a separate enclosure so I can unplug it from the directional coupler and use it for Amp gain/phase etc. With additional of a PIC micro and LCD display it could be programmed to provide various measurement types.

There are construction details in the ARRL Antenna book for a fixed gain antenna that looks good for a reference.

Hopefully this will give me a suitable arrangement for setting up 900MHz band antennae using the sig gen power levels.

Regards

David

Yeah? When was the last time an atheist:

- rode an airplane into a building?
- killed a doctor?
- bombed a planned parenthood clinic?
- scammed people put of their money in the name of atheism?
- blew himself up, as well as dozens of innocent civilians?
- imprisoned, oppressed, tortured and murdered various minorities simply because of their religious orientation?
- attempted to introduce superstitious nonsense into the public schools' curriculum?
- withheld medical help or vaccination, genitally mutilated or otherwise endangered the life of a child on the basis of his atheism?
- attempted to impose his own brand of "morality" that denies basic freedoms, liberties and other human rights to all sorts of people?
- started a war, religious genocide or mass murder in order to promote atheism specifically?
- formed a cult that sexually abused children, financially and physically drained the followers, then convinced them to commit suicide or simply killed every cult member?
- promoted legislation, laws and even Constitution change based on cherry-picked bullshit from some scripture?
- encouraged other atheists to kill as many non-atheists as possible?
- and so on...

> Fred brings up an interesting point. Atheism IS a RELIGION!!

Sure, also war is peace, freedom is slavery, ignorance is strength.
Isn't Newspeak grand?

> I define RELIGION as a set of beliefs that influence behavior.

And I define black as white. Is today International
Pull-a-definition-out-of-your-ass Day or are we applying the Bush
administration doctrine to everyday life now?

Fair call - guess it is an indicator of how ridiculous and off topic that
this thread has become. Religion will always be a divisive issue but it
really has no place in any of these NGs - can we please either end it or
move it elsewhere to somewhere more appropriate?

Matt

>That's especially true when faith is blind...

Well, in fact, the faith (by Godel's criteria) has nothing to do with
being blind, or by avoiding examination at all. By Godel's proof,
that broken rule of addition comes from inspection and rigorous
application of the rules. Self-contradiction is an inevitable
consequence. If you cannot accept the contradiction, then you lack
faith. Mark it up to "the Mystery."

The reason is that one cannot "know" when one is part of what is
trying to be "known." Another metaphor is that one cannot completely
describe the field, if one is standing within the field (the observer
can not see everything at once, and must be obstructing some view, if
only to be standing on it). Hence all knowledge is incomplete unless
you can withdraw into another dimension (or by stepping over the
field's fence into a greater field encompassing it).

Godel then points out that at that point of extra-dimensionality (when
you become a minor deity), you are still faced with the same problem:
you cannot possible "know" everything about the field within which you
stand, because in this new dimension you are once again obstructing
your view to some portion of it.

Math can only accurately describe a subset of experience, never its
whole. Same problem resides in all the religions without exception.
The only time Man did not have this problem was before the "Fall."

This state is what is also called Nirvana. By all accounts, Man will never walk with God again.

Of course, others may beg to differ, and suffer the consequence of explaining why they cannot explain:

1 + 1 = 3

variously heard in prayers (OK, wails of grief) as:

"Why ME?"

To confound the pious who reject science, they suffer the most from lack of faith. Evidence Lord Kelvin's statement:

"The more thoroughly I conduct scientific research, the more I believe that science excludes atheism."

The fumbling attempts to rewrite Darwin, replacing it with untelligent design, are heretical works of apostasy.

Hi Walt,

Using the mouse, hi-light the text of interest and on the keyboard
press the two keys (at the same time) <ctrl> C. This copies the text
to the clipboard. Then, in your open, new post, place the mouse
cursor where you want the quote (click the mouse to put the cursor
there). Then on the keyboard press the two keys (at the same time)
<ctrl> V. This will transfer the contents of the clipboard into the
text area.

Hi Walt,
Is the "copy of text" an ASCII text section or a graphic
of some sort? For graphic text, some of us use OCR software
as graphics (binaries) are not allowed on this newsgroup.

Thanks, Richard, I knew how to get the text onto the clipboard, but I didn't know that ctrl V would 'paste' it into the text portion. There is no 'edit' or 'paste' button in the 'new text' screen.

Hi Cecil,

My copy is ASCII, which appeared in the starting msg of this thread. I composed in Word, and my older Word programs allowed one to convert to plain text with CR at the end of each line. The 2003 ver doesn't allow that, and the lines run to 256 characters per line, which my first post on the thread did. But Richard C. just informed me how to paste when there is no 'paste' button available. I'm going to post my msg again, and we'll see whether its lines end correctly, or with 256 characters per line.

Walt

885. Second try with Beverage Antenna in WW2

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-22 17:51:56 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <7or5j1dkir93jfr67nh57gft0r99eul5g3@4ax.com>
Source record: 70282

As a monitoring officer with the Radio Intelligence Division (RID) of the FCC in Hawaii during WW2 I was privy to some interesting situations. Our State Department was of course aware of the operations occurring in the Pacific Theater. The people there were also aware of the propaganda being spewed by the Japanese short-wave broadcasters. But State was curious concerning what the Japanese living on the homeland were being told-were they being told the truth, or the same propaganda as told on the short-wave broadcasts, or a totally different story. State asked the RID to determine whether we could obtain such information.

We cruised the AM broadcast band and found several nighttime signals from Japanese mainland stations, but most were too weak to copy. However, JOAK, Tokyo, on 650 KHz was S9, but there was a problem in copying it. KFI, Los Angeles, was also on 650 KHz with an S9 signal-copying intelligence from JOAK was impossible. How can we eliminate, or reduce KFI's signal level. A Beverage Wave antenna, perhaps?

We then proceeded to the northern portion of Oahu and constructed a Beverage one-half mile long, five feet above ground, aimed at Tokyo, and terminated with a 1000-ohm pot resistor to ground at the Tokyo end. We discovered that by varying the pot resistance we could null the KFI signal to almost zero. The resistance terminating the Beverage that produced the null was around 600 ohms. Because the matching resistive termination rendered the Beverage a traveling-wave antenna with no standing wave, the signal from JOAK was terminated by the input of our receiver, while the signal from KFI was dissipated in the matched resistance at the Tokyo end of the Beverage-no KFI signal reflected toward the receiver. Voila-JOAK was perfectly readable for recording!

We sent the first recording to Washington, and State was delighted-requesting that we continue recording JOAK continuously. Consequently, our recordings were flown daily to Washington from Hickam Field in Honolulu. We were left in the dark concerning the information on the recordings, and how it affected the War effort, because State didn't share it with us. But it must have been pretty good, because State was on our case every day to make sure we sent them the recordings.

Hi Matt,

As so well demonstrated in the historical record, ethics and religion
are not the same thing. To say atheists lack any counter (ethics) is
also shown in the historical record to be wrong. By some accounts,
Buddhism has no god, is quite ethical, but also quite atheistic. This
could also be applied to Jainism. Unitarians hardly demand the
existence of God, the imposition of beliefs is not in their code,
whereas their ethics are guided by rational thought rather than
external authority.

Source record: 70286

Most interesting story. I suspect that this may have been the precursor to CIA's Foreign Broadcast Information Service (FIBS...pronounced by those in the trade as Fibbis). CIA has these overt monitoring posts to pick up broadcasts from a whole host of stations. These are transcribed and translated into English and put in a daily summary. They are unclassified and freely disseminated at least within government. They are quite distinct from monitoring for intelligence purposes and totally different personnel participate. The FBIS folks are often foreign nationals hired as contract workers and as such do not participate in intelligence analysis or see intelligence product (except for CIA's cleared managers.)

On a humorous note, early in my ham career about 50 years ago, there was another kind of beverage antenna. CQ magazine published a story on building a 40 meter vertical antenna by soldering end to end sufficient numbers of beer cans to reach the required 32 feet. Beer cans I guess were made of ferrous products back then (I was too young to drink at the time.) Several letters to the editor pointed out that the same thing could have been accomplished by 32 feet of aluminum tubing which of course was true. I think the same article also had an accompanying matching coil made out of semi-flexible copper tubing which the author said he straightened out prior to coiling in the appropriate size in what he described at "the time honored method." What he did was secure one end of the tubing to a vise on a workbench in his garage, secured the other end somehow (don't remember exactly how he did this) to his automobile and then straightening the tubing by slowly driving forward.

Several follow-on stories appeared following publication, most dealing with the process of acquireing the requisite number of beer cans. One author did what today we would call a blog as he tried to acquire the cans all at once by drinking the contents. As the story progressed, his written words became more and more unintelligible.

I am far too young to know about these WW II stories first hand (I was born in 1942), but I did have a long career in Signals Intelligence and I had heard some similar stories from my earliest supervisors, most of whom were WW II veterans.

Thanks for sharing this with us.

Two half waves in phase, colinear. The 1/4 wave shorted "stub" is perhaps
the easiest way to get a 'good" 180 degree shift to get the segments in
phase. Used from early antenna design times...

Roy,
I'd appreciate your further comment on this. I 'know', from history,
that the spacing of two collinear half waves in phase affects the gain and
that there is an optimum spacing for gain that places the two collinear
elements apart (not close enough for a 1/4 wave shorted stub to be used for
a common feed). I had theorized that this "optimum" spacing results in the
most compressed lobe (without excessive secondary lobe formation) which is
simply due to the far-field phase summation of the two elements radiation.
Is this different than the mutual coupling to which you refer, or is this
another effect?

You should probably have a look at http://users.adelphia.net/~n2pk/. Paul has done a nice job on a vector network analyzer project, with some good additions from others, and you can probably pick up quite a few nice ideas from that design, maybe even use a lot of it.

The single parallel strip really does pick up both forward and reflected, and if you can terminate it properly at both ends (especially the forward end) so that the load there does not reflect back down that line segment, you can sense both forward and reflected on the single parallel strip. Making the load really be 50 ohms isn't easy when it also has to be a detector, though, so two strips may make more sense for you. It should work fine to have them just be symmetrical, one on either side of the main line.

If you really care about phase detection, be aware of the phase shifts through line segments. Such couplers are sometimes called quadrature hybrids. The sampled forward output will be in phase with the applied input, but the through-line output will be delayed 90 degrees (a quarter wave in the transmission line, obviously). The sampled reflected output will be in-phase with the reflected that arrives at the through-line load port--by symmetry. But that means you'd measure a 90 degree phase difference between the forward and reflected, for a case where they were in phase at the through-line output port. Hope I have that all correct...if not someone will probably jump in and correct it. It should be easy to calibrate out. Since the phase shifts are frequency-dependent, if you want to cover much of a percentage frequency range, be prepared to handle frequency-dependent calibration. The coupler goes out of quadrature, and you probably won't have exactly the same length lines from each coupler to the detector.

Since the parts are really pretty cheap and replicating PC boards is straightforward, you might think about the advantages of NOT having to disconnect things, and the expense of putting good RF connectors on the coupler, and maybe just build the detector into the coupler, and make a separate one for other uses. A couple good SMAs and the hassles of connecting and disconnecting a few times should pay for just buying another $20 part. Half a tank of gas these days, huh?

Cheers,
Tom

Science has nothing to do with faith because the essence of science is
to continually ask questions, and explore new possibilities. IOW,
science is readily open to change, and will admit it's mistakes if
close examination of evidence reveals such things to be so. OTOH,
faith is rigid, and is not subject to any change among those with
"true believer syndrome." Faith, especially blind faith, expects one
to believe without asking any questions, and just accepting things as
they are presented.

Jon, I'm pleased that you found my story of interest. I have just put together another war story that I may post tomorrow. It concerns how the FCC saved thousands of military personnel and more than 600 aircraft from ditching in the sea between the mainland and Hawaii during WW2.

And yes, Jon, I remember the beer can article. A cute one, to say the least.

It's actually the same effect.

If we assume no loss (a reasonable assumption for this kind of antenna), all the power applied to the antenna is radiated. So any change in gain is accompanied by a change in pattern -- if there's a single major lobe, the more gain you have the narrower the lobe is. But if the element currents are in phase, there will always be a maximum broadside to the array regardless of the spacing, because the fields from the elements will always add in phase in that direction.

But why is the gain different for different element spacings? You get different gains for different spacings, which means that the sum of the fields changes as you change spacing -- and this means that the field from each element changes as you change the spacing. If you put 100 watts into the array, each element will radiate 50 watts, again regardless of the spacing. So why does the 50 watts produce a larger or smaller field broadside to the array as you change the spacing? What's happening?

As the spacing changes, the mutual coupling between elements changes. This alters the feedpoint resistances (and reactances, which aren't important to this discussion) of the elements. And this in turn modifies the amount of current flowing on each element for that 50 watts of applied power. (It can be more reasonably argued that the mutual coupling changes the current, and that changes the resistance. Or that the mutual coupling produces a feedpoint voltage which alters the current and resistance. But you reach the same conclusion via any of those paths.) The essential fact is that the field gets stronger or weaker as the element current increases or decreases as a result of mutual coupling. The combination of the changed pattern shape due to spacing and the changed maximum pattern size due to mutual coupling

always result in all 100 watts being radiated.

Chapter 8 of the ARRL Antenna Book has a graph of gain vs spacing for two half wave elements placed end-to-end, compared to a single half wave element. The gain peaks at about 3.2 dB at a spacing of about a half wavelength. When the elements are very close, as they are in the super J-pole, the gain is only about 1.6 dB greater than a dipole. That's why I felt the J-pole gain wouldn't be as high as claimed.

Note: The current distribution on the elements also changes as a result of mutual coupling -- see http://eznec.com/Amateur/Articles/Current_Dist.pdf. But I don't believe the effect is very significant on a collinear array with thin elements. Anyone wanting to find out for sure, though, can do so with EZNEC or a similar program.

Roy Lewallen, W7EL

Probably by clamping it to the bumper! Back in those days we had 'real'
bumpers -- Made In America _and_ made out of steel. As well, the dash
'board' was made out of steel.

Back on topic: Great Story(s).

Tom,

Thanks for the link. This unit only goes to 60MHz so needs a lot of mod
to get it up to 900MHz where I am working.

I have found this one that does go up there
http://www.geocities.com/robert_lacoste/previous_designs.htm

Some of the parts used in his design are getting difficult to obtain so
I am thinking of replacing the Cypress device and prescaler for a
LMX1600 PLL and driving the generator ramp via a PIC micro controller
instead. The VCOs, Splitters and Amp are all still available.

Before I start on this project I will make a manually adjustable version
(The directional couplers will not be redundant)

The reason the detector head is a separate item is that this will be
inside a small shielded area inside the main box that also has the micro
controller, LCD display, keypad and serial port.

Then I can simply swap the 900MHz coupler for the 433MHz coupler to
change bands.

I have completed the artwork for the Bi_Directional coupler and will
make the PCB today. Using RFsim99 I was able to play with combination of
track widths and gape between mainline and coupled lines to get the 20dB
coupling and 50 Ohms.

Hi Matt,

This looks like a homogenous world point of view, where those who are
____, are not; and those who are not ____, are. A circularity that
fails in science, but certainly has served religion through the ages.

Consider the enigma of:
>Sociopaths may be the only true atheists;
is a mechanistic approach to morality, which is amoral.
>the rest are simply uninformed of their own dogma.
And to distinguish them from the informed (and not simply those who
disagree):
"kill them all and let god sort them out."

Hmmm, that's how we got here.

Hi Walt,

In fact Agent does have these buttons, you simply haven't customized
your tool bar to display them:

Menu item: Tools, select Options Dialog, then Navigation and Menus
Panel, finally Toolbars. This presentation allows you to customize
all the buttons.

In the composition window (where you write your posts) there are three
paste buttons available.

You are running on version 1.93. According to Forte:
If you are a registered Agent 2.0 user or you bought Agent 1.93 on or
after December 9th, 2003, you don't need to purchase an upgrade. Just
download and install Agent 3.1

There are new features, but you may not appreciate them if you simply
use Agent out-of-the-box.

Once upon a time, we didn't know the nature of light, or lots of other
things. And some people used your same argument.

May I suggest that without faith, there is no science. Most

Matt, you are simply incorrect.

Just about every Roman Catholic pope that served from about 300 to
1600 C.E. I don't know their names, but I'm pretty sure there were
more than three during that time period...

You really need to study Ayn Rand's take on Objectivist ethics.
The objective thing to do is to grant to everyone the rights
that you require for yourself, no matter what you believe. It
bears a close resemblence to the golden rule.

The difference between me and you is that I know it's always wrong, and
you seem to have left an opening for your "religion" to do evil things
becuase your morality says it's ok.

I'm sorry that you can't understand that an atheist can have morals not
tied to superstition, but to to true right and wrong.

"Everyone has to believe in something."

I guess I'll believe in Bokonon.

In Cat's Cradle, Kurt Vonnegut, Jr., created a new religion, Bokononism. The holy scripture of Bokononism was "Books of Bokonon", written by a spurious holy man named Bokonon as a way to distract the people of San Lorenzo from their pitiful lives.

What is sacred to Bokononists? Not god; just one thing: man.

Here, to set the tone, are the opening verses of Book One of Bokonon

Verse 1: All of the true things that I am about to tell you are shameless lies.

Verses 2-4: In the beginning, God created the earth, and he looked upon it in His cosmic loneliness.

And God said, "Let Us make living creatures out of mud, so the mud can see what We have done." And God created every living creature that now moveth, and one was man. Mud as man alone could speak. God leaned close as mud as man sat up, looked around, and spoke. Man blinked. "What is the purpose of all this?" he asked politely.

"Everything must have a purpose?" asked God.

"Certainly," said man.

"Then I leave it to you to think of one for all this," said God.

And He went away

This tired old argument???

First of all I notice that you haven't addressed any of the specific
examples I gave about *theists* and their religious crimes.
Second, all of the examples I gave are about theists committing crimes
against humanity precisely *because* of their religion, directly and
indirectly.
As far as "Stalin, Lenin and Mao" are concerned, their crimes were most
certainly not committed in order to promote atheism, unless that atheism
was a vehicle for establishing communism, which btw, is de facto a form
of religion. Religion was not outlawed in the USSR and priests were
being prosecuted no more than the rest of the society. Communism and
theism can co-exist and did successfully in most communist countries.
Besides, Stalin spent years in a seminary. Some atheist.
One could just as successfully argue that since "Stalin, Lenin and Mao"
committed crimes and they all ate bread, then by your logic people who
eat bread are murderers.

> that the religious, despite their failures, have improved the human
> condition immeasurably where atheists have been only a blight upon
> civilization.

??? You have got to be kidding? What has religion possibly done for
anyone except provided false hope while stealing their money?

Stifling science (from Galileo to stem cells), witch burning, condoning
slavery, religious genocide on unprecedented scale, eradicating whole
civilizations, oppressing women, condoning fascism and
national-socialism, suppressing human rights for minorities, huge waste
of resources that could be better spent elsewhere, contributing to
millions of dead from AIDS by banning contraceptives, flaming national
and religious intolerance from Ireland to Palestine, and I could go on
forever...

As for your "blight" comment, a majority of scientists are atheists, for
example. The percentage increases with education. That's education *not*
Kansas style.

Hi Matt,

Well, in fact the contradiction originated with your statements. No
one else theist/atheist posited them. As to what is "believed" by
anyone, that is a speculation when it is expressed by a third party,
you about "them" (whomever they may be).

>I'm still waiting for an atheist to explain how it is
>that he can have a moral point of view and not have a religious dogma.

Unfortunately, you've presented yourself as being the arbiter of who
is an atheist, and denying that classification of them by your own
test. This is self-fulfilling prophesy.

924. Wooden I section pole

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-23 05:45:41 UTC
From: Cencom <Cencom@Maine.RR.Com>
Message-ID: <9EMYe.89486$EX.17784@twister.nyroc.rr.com>
Source record: 70321

John,

The general rule-of-thumb for a utility pole installation in sort-of normal soil is 10 percent of the pole's length, plus 2 feet in the ground. For example, a 40 foot pole would be placed in an augered hole 6 feet deep, leaving 34 feet above ground. The hole should be back-filled and tamped to provide support for the pole. No concrete is needed.

Thanks for your comments. My current thinking on this matter is to purchase a 35 or 40 feet hinge base fiberglass flagpole. Going this route costs a few bucks, but the flagpole only weighs about 75 pounds and can be moved in the event that I change QTHs. http://www.excelsails.com/flagpole.htm

Bob, the Beverage wasn't used for its ability to receive weak signals, but for it's capability of rejecting the unwanted signals, KFI in LA in this case. Terminating the long wire of a Beverage makes it a traveling-wave antenna, in contrast to the usual standing-wave antenna. Consequently, with the termination at the end opposite to the direction of the unwanted signal, the unwanted signal travels to terminating end and is dissipated there. Because the resistive termination is equal to the Zo of the antenna the unwanted signal is dissipated with no reflection. Therefore the receiver doesn't see the unwanted signal.

Thanks, Dave, for mentioning this. In my case the pole will be supporting an octagon shaped loop made out of 100 feet of 3/4" copper pipe. The top of the loop will be several feet below the pole top, and if necessary I will guy the top of the pole.

933. The Correct Polarization Saves Lives During WW2

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-23 15:21:38 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <s078j11fada7cgj0jplj17qfqq83qgk15l@4ax.com>
Source record: 70230

During WW2, Prose Walker, W4BW, (then W2CXA) in 1942 became Chief of the Radio Security Center (RSC) of FCC's RID, located in the Dillingham Building, Honolulu. (Long after WW2 Walker was Chief of the Amateur Division of the FCC, succeeded by John Johnston, W3BE, President of QCWA.) In his position as Chief RSC Walker learned that many military aircraft and its personnel were being lost at sea while traveling from the U.S. Mainland to Hawaii. There were two reasons for their being lost, 1) 'navigationally impaired' pilots (bureaucratese for 'lost'), and 2) totally drained fuel tanks. There was naturally a limit to the size of the fuel tanks, but what caused the pilots to become navigationally impaired? That point preyed on Walker's mind, and on investigating he discovered a deplorable situation that needed fixing. Here's what he found.

At the Boeing aircraft plant in Seattle they were building bombers as fast as possible. Dozens of green flight teams just out of flight school were awaiting their new aircraft, and anxious to get aboard and proceed to the South Pacific area as soon as possible. The navigators and radio operators were taught how to use the loop direction finders that were standard equipment on the aircraft. But they were never told that loop DF's were incapable of obtaining reliable directional information from signals propagated by sky waves. The DF's aboard the aircraft were capable of delivering reliable data only when the electromagnetic energy in the received signals is vertically polarized, but the navigators and radio ops didn't know that. Unfortunately for them, on reflection and refraction through the ionosphere, a linearly-polarized wave is converted into an elliptically-polarized wave, resulting in a continual shift in the null obtained by the loop DF as the polarization angle of the incoming signal rotates elliptically during propagation. Consequently, once the aircraft has left the mainland, and can no longer receive the vertically polarized waves from AM broadcast stations, the only reception remaining is from sky waves propagated far beyond the range of the ground waves of the AM stations. Therefore, bearings taken from the loop DF's aboard the aircraft when at sea beyond the ground wave signal were useless. The only remaining means for the navigator to determine the position of the aircraft was through celestial navigation, using readings from the sun or stars. The situation gets pretty bad on cloudy days, and that's when the pilots became navigationally impaired.

At this point Walker came up with a solution that ended the era of lost aircraft flying between the mainland and Hawaii. Fortunately, every FCC monitoring station in the U.S., Hawaii, Alaska, and Puerto Rico had Adcock direction finders as standard equipment. Adcocks, as you probably already know, are susceptible only to the vertical component of the arriving wave, regardless of its angle of polarization. Therefore, instead of constantly wandering, as with the loop DF, the null obtained appears at constant angle on the Adcock scale, even though the angle of polarization of the arriving wave is continually rotating elliptically. In other words, Adcocks give accurate directional information obtained from sky waves. Walker's reasoning was that triangulation from bearing measurements obtained by the FCC Adcocks taken on signals

transmitted from the lost aircraft could determine its precise location, and thus determine a course to fly directly toward Hickam Field in Honolulu. The problem then was how to organize the communications to achieve the necessary procedure. Walker organized it in this manner:

The CAA (then the Civil Aeronautics Administration) had a terminal in Honolulu with facilities for communicating with all aircraft. A direct teletype connection was setup between the CAA and the RSC, which had a kilowatt transmitter used to communicate with the secondary monitoring stations on all the Islands, each of which had Hallicrafters HT-9 transmitters. When the pilot of the aircraft determined they were lost, the radio operator signals the CAA, who instantly puts the aircraft's frequency on the teletype and rang its bell, alerting the RSC operator of the situation. The RSC operator then sends the following message to all secondary stations that continuously monitor the RSC frequency: "LOS LOS LOS 4250 4250 4250," where LOS meant lost aircraft and 4250 was the frequency being transmitted by the aircraft. The operators of the Adcock DF stations immediately tune to the 4250 KHz frequency, hears the aircraft, and begins taking continuous bearings. The aircraft is sending long dashes, MO MO MO, to enable the DF operators to be certain they're hearing the right signal, and obtain a satisfactory bearing angle on a moderately constant signal.

As each bearing is taken by all stations, the bearing angles are transmitted to RSC, where a great circle map of the entire Hawaiian area is hanging on the wall. A compass rose is printed on the map at the location of every monitoring station in the Islands, with a hole in the center of the rose through which a weighted string is hung. A pin is attached to the opposite end of the string to secure the string at the desired point on the map, with the string stretched over the angle on the compass rose indicating the angle of the bearing obtained by that particular station. As the strings representing each station reporting are secured they intersect at the point indicating the location of the lost aircraft, the intersection point called a 'cocked hat'. It was usual for the aircraft's position to be determined within ten minutes after the pilot alerted the CAA of its being lost.

After the aircraft's position is located it is then given a course to fly toward Hickam Field, and the bearing measurements are reported continually until the pilot can see the Field. During this time the aircraft's location is followed all the way in to the Field, thus verifying the accuracy of the bearing measurements and the pilot's success in following the directions.

Once Walker's plan was in operation no more aircraft were lost while flying between the mainland and the Hawaiian Islands. In 1943 alone, 273 aircraft were saved by the FCC Adcocks, and more than 600 were saved during the duration of the War.

Unfortunately, planes were continuing to be lost on the run between Hawaii and the South Pacific, so Walker was invited by the Military to investigate. What he found was almost unbelievable. The Army Air Corps was using Mercator Projection maps for those runs, unaware that using maps of that projection produced directional errors of humongous and fatal proportions. On Walker's advice, once they acquired new maps with great circle projection, the number of lost planes dropped to zero.

This is just one of the stories of how the FCC assisted in the ending of WW2. I was privilged to have been one of the bearing takers.

>anybody else should be the arbiter?

Hi Matt,

A very strange question. You offer it in terms of a projection. The question:
>So you think everyone else should be the arbiter?
Is phrased not about a neutral subject, who should be arbiter, but rather is couched as do I think....

The neutral context would have simply asked: Who should be arbiter?

What I think is expressed by me, not you. You might ask questions, but phrasing them in speculative terms and projecting them into my mind is a prejudicial bias.

>Once again though, we digress from the argument. Does an atheist
>believe in anything outside himself? I submit that he most certainly
>does. You have admitted as much when you introduced ethics which
>requires a basis.

See what I mean? You have injected your own belief by asserting I made an admission. An admission is a loaded statement in a Christian cultural context relating to guilt. You could have as easily pointed out I raised the subject, which is a neutral observation. As such, this bias is inserting itself as a judgment of the moral validity and application of otherwise bland statements.

>Feel free to present an argument that rebuts any of those points.

Once you free yourself of contextual prejudices.

Things I have learned from watching the news about Hurricane Katrina on TV:

1. The hurricane only hit black family's property.

2. New Orleans was devastated and no other city was affected by the hurricane.

3. Mississippi is reported to have a tree blown down.

4. New Orleans has no white people.

5. The hurricane blew a limb off a tree in the yard of an Alabama resident.

6. When you are hungry after a hurricane destroys your property, steal a big screen TV.

7. The hurricane did 23 billion dollars in improvements to New Orleans: now the city is welfare, looters and gang free and they are in your city.

8. White folks don't make good news stories.

9. Don't give thanks to the thousands that came to help rescue you, instead bitch because the government hasn't given you a debit card yet.

10. Only black family members got separated in the hurricane rescue efforts.

11. Ignore warnings to evacuate and the Government will come get you and give you money for being stupid.

12. Oh, and it is all George Bush's fault, not the mayor's or Governor's.

That is simply not true. An athiest is, by dictionary definition, one who denies the existence of any god(s). He or she may very well have a sophisticated (or simple) system of morals and beliefs that exclude gods.

"Agnostic". Look it up. An athiest denies the existence of any god; an
agnostic says it is impossible to know.

Your vocabulary needs work. "Atheist" does not mean lack of faith. An athiest HAS faith ... faith that there is no god. One can have faith in his/her ideals, friends, a million things, and still be an athiest.

Jeeze, do y'all speak English or own dictionaries? Athiests DO have faith in
their beliefs, one of which is that there is no god.
>
> Law itself is derived directly from religious thought. If there were

That is so absolutely wrong that it is hard to explain. Dictatorships *do*
have law. Check out Hitler's Germany, Franco's Spain or, more recently
Saddam's Iraq - all with stringent legal codes and none athiestic. OTOH,
there are legal systems, Marxist Russia for example, that had plenty of laws
but denied the existence of any god making them athiestic.

954. Fractal Antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-23 18:36:05 UTC

I is said that Cohen and Robert Hohlfeld has proved
mathematically that for an antenna to work equally
well at all frequencies, it must satisfy two criteria:

1. It must be symmetrical about a point.

2. And it must be self-similar, having the same basic appearance at
every
scal.

That is, the antenna has to be "fractal."

Does anyone know how this "theorem" was proved?

I posted this on the wrong newsgroup a few days ago and no one has answered, so I'll try here.

I have a Butternut Vertical (as a secondary antenna) and a regular radial system set up with it. I also have a metal roof on my house (here in the country in Western Washington). I have been wondering if I can use the metal roof as the radial system/ground plane for this antenna. Haven't tried it yet. Would this work or would it detune the antenna?

What do you guys think?

Hi Harry,

The correct question is "How many times has it been disproved."

So many times that those authors have abandoned the contest in shame.
After-all, can you point to a single instance of a fractal antenna
that does not carry so many constraints to competition that it doesn't
suffer the enigma of being an accidental discovery rather than a proof
of concept?

Basically what is being alluded to as this "theorem" is simply Zen
archery. After a shot "arrow" of specific design was discovered to
have some virtue, the "target" was painted around it and called a
theory.

How many examples would prove otherwise to disqualify the
theory/theorem? I can lead you to several hundred pages of results if
you really care.

Hi Rod,

It would be simpler to just do it and see what happens. The worst
that comes of it is that the metal roof needs the sections
electrically bonded together. Not so much as a "ground plane" as to
reduce corroded connections (by bridging and shorting them) that act
as semiconductors and thus give rise to spurious emissions.

Any elevation removes your antenna from the deadly embrace of lossy
ground.

Of what use, if the theorem exists, is a fractal antenna anyway?

It cannot perform any better than any other antenna of similar overall dimensions and in some respects, given the opportunity, it will do worse. Just like the discredited E-H antenna it is wishful thinking.

First Crusade:

12,000 Jews killed in the Rhine valley.
6000 killed in Jerusalem when they torched the synagogue there
30,000 Muslims killed at the al Aqsa mosque.
at least 200,000 killed over the length of the crusades.

Then let us not forget the Iquisitions, witch-hunts and other jollies
that went on.

And there is plenty more to go around on all sides. Appears

We're a long way from "a few thousand".

But as the recent poster Mike has noted, this is pretty off topic, so
I'll refrain from any more posting in this thread.

I did that once with a HF6V and a metal roof about 40' above ground.
It seemed to work fairly well. The tuning on the Butternut is fairly
touchy on several bands, so yes, you will probably need to retune it
between roof mounting or ground mounting (I did).

While many would agree with you, fractals have been used in graphics to produce images that rival artists. For instince the images used to display Spock's Planet in the Star Treck movie were created using fractals. I beleive that the images of one of the Mars video's that NASA uses to show the surface of Mars is created using fractals to generate the 3-D images.

FYI, quote fron Fractal Antenna FAQ webpage at:
http://www.fractenna.com/faq/faq.html

Q: I understand that fractals have been used to solve an old problem from Maxwell's Equations. What is that?

A: In 1999, Fractal's Nathan Cohen published an article solving a basic problem: What are the requirements to make antennas frequency invariant? A later article by Robert Hohlfeld and Nathan Cohen then analytically showed that you need origin and self symmetry (self similarity) for this to occur in Maxwell's Equations. The implications are profound for antenna design, as a previous but less universal explanation by Victor Rumsey, made nearly 50 years ago, was shown to not be the total picture. The necessary and sufficient conditions for frequency invariance have been dubbed 'HCR Conditions', after the three contributors to solving this age old problem.

There are no such things as "good" and "evil" or "right" and "wrong".

Except as opinions which depend on the point of view from which an individual may perceive events. Points of view are randomly distributed and depend solely on one's self-interests and one's location in space relative to the crowd.

Self interest is the keyword. But distant events (as most of them are) in time and space are rapidly attenuated in their effects on one's opinion. Which results in most people's opinions being neutral about most things, neither good nor bad.

Which is just the same as saying most people just don't think about things unless things are in their immediately vicinity. People are naturally mentally bone idle. As with all lifeforms, this conserves energy which is always in short supply.

Reg.

Along with a lot of good people as well, same with the Texas coast. So
if God has all this power, why does he have to destroy a city and good
people just to get rid of a few bad ones? Why doesn't he just strike the
bad ones dead? Why use a hurricane?

Hi Harry,

There is a lengthy experience with such proclamations made here, by
those authors. The long and short of it is there is more crafting in
the language than there is in the theory being explained.

For one, who is credited with asking the "question?" Follow that lead
and you will find a sort of Mutt 'n' Jeff dialogue of mutual
convenience.

Simply by examining this language reveals that it is
self-congratulatory. For example, this alone:
>A: In 1999, Fractal's Nathan Cohen
Who, or what is Fractal to associate the possessive Fractal's?
or
>solving a basic problem
you may notice that this "problem" is never even discussed within the
context of your snippet, and throughout the entire page its meaning
shifts to suit the pitch.

Presumably it is
>What are the requirements to make antennas frequency invariant?
but through the crafting of language, that is not explicitly the
problem, nor is the paper the solution. The paper is "about"

> What are the requirements to make antennas frequency invariant?
which is a field that had been already tilled 50 years ago, and it wrought the Log Periodic forms described by Isbell, and the helices of Kraus. No, it takes an invented term, a forced definition, and claim grab to accomplish this "new" invention.

Problem is (and this is the nut of the case), no one in this "field" of fractals can point to an algorithm or calculation and say that this term describes the feedpoint impedance and that term relates to the radiation performance. Two qualities that any antenna savant would be interested in, but wholly missing from these "theories."

As I've offered hundreds of fractal examples (and I'm not too surprised to see zero expressed desire to see them), and in comparison to these merchandisers of rhetoric, they hardly rise to the level of what would be called antenna research. Their repertoire is painfully limited, certainly not unique, and has been shopworn for years. As a topic in this forum, you are among the rare questioners that drift in and then out. The topic is not self-sustaining beyond the morbid interest in the side show of freaks of nature.

It was left to the marketing department.

I would urge you not to speak in doubting words about fractal antennas.
Should you fail to heed these words you will be added to the long list of
sue-ees...

It is my opinion that the Cohen circle jerk will continue to share a group
of devotees with the E/H and CFA inventors. Junk science is applied to areas
other than global warming...

There is nothing magic about a fractal, and other forms have proved equal or
superior to it as an antenna.

The thought occurs to me that depending on the number of iterations you take the fractal equation to the longer the length of the fractal. If you work the length enough you will get both resonance and impedance match out of a fractal antenna. Maybe that's how they work.

Reg, there are more practical applications. It is a long time since I worked in the field, but fractals provided a good method (economical on data, realistic visually) of surface texture rendering in computer modelling of solid objects (eg roads, brickwork, stucco, etc).

Hi David,

Common experience teaches us that a bent clothes hanger replacement
for an automotive antenna works too, but this reveals nothing of why
beyond the commonplace explanations available for the last 100 years.

I covers length and iterations count and ... Which is more work and
more results offered by the entire field of fractals. To what end?
That this topic, due to its monstrous complexity could only survive in
the millimeter scales now used - and then only as a marketing lever.

"Agnostic" is a cop-out word for someone that doesn't want to admit
that they're an atheist. It just sounds nicer. If you say that it's
impossible to know if there is a god or not, you obviously don't
acknowledge the existence of any god. That makes you an atheist.

Hello Cecil,

That's very good advice!

> The objective thing to do is to grant to everyone the rights
> that you require for yourself, no matter what you believe. It
> bears a close resemblence to the golden rule.

Sounds identical to the golden rule to me!

IIRC, a fellow named Hobbes worked out the golden rule by pure logic a couple of hundred years ago.

While Objectivism has some obvious defects and shortcomings, it is well worth studying because it develops a coherent system of ethics with a minimum of reference to unprovable claims.

For example, Objectivism has as one of its basic concepts that each person has certain basic rights as a human being, such as each person owning their own life. All forms of involuntary servitude, except as punishment for a crime, are completely immoral under Objectivist ethics.

Another Objectivist concept is the initial innocence of each person. The concept of inherited guilt, usually called 'original sin' by many religions, is incompatible with Objectivist ethics. How can anyone be held responsible for the actions of a long-dead-before-you-were-born ancestor?

--

Of course a lot of this discussion circles around because of faulty logic and too-loose definitions. For example, what, exactly, is an atheist? What, exactly, is a religion?

Suppose someone believes in God - but also believes that one of God's most basic commandments to human beings is that they *use* their

brains, logic and experiences to know His creation and their purpose in it, and that they must continually question anyone who tells them they must accept anything without proof.

What do you call such a person?

================================

Owen, yes, I know.

But radio antennas is not one of them.

Do you know of one which performs any better than any other sort of
antenna?

Just calling it a fractal doesn't make it marvellous although, for
CB-ers, it may increase the sales volume.

Remember the E-H antenna which abused the works of James Clerk
Maxwell? Fractals fall into the same category. They serve only to
increase the complexity of modelling programs!

Reg.

992. The Cavity Magnetron.

==========
"Joe McElvenney" wrote
> Randall and Boot's cavity magnetron
> didn't really come onto the scene until about 1940.
>
==========

R & B's cavity magnetron was developed at Birmingham University in the midst of the air raids on that industrial city. We can imagine R & B having to hide under the workbench whenever a descending bomb was heard, culminating in a loud bang and broken glass.

The ingenious device generated a peak pulse power of 50 kilowatts at 3000 MHz. Pulse repetition frequency 400 Hz. Pulse width 1 microsecond. So far as I can remember there were 6 or 8 cavities milled into the copper block. Alternate anodes surrounding the cathode, and close to it, were strapped together at their ends via copper bars. The block diameter was about 2" and about 1" thick. The magnet was a U-shape with pole-pieces which closely fitted the flat ends round the block such that the magnetic field was parallel to the cathode.

Because the luftwaffer in 1940/1 had more bombers than the RAF, and in view of its potential as a war weapon, Churchill personally banned installation in RAF aircraft in case the top-secret device should be shot down over Germany and fall into the hands of German scientists and engineers.

So Churchill handed the cavity magnetron to Roosevelt as a free gift in return for 50 rusty, old, WW1 destroyers. The manufacturing capacity of the US radio industry far exceeded that of the UK. Not to be outdone, the Americans soon produced a 10,000 MHz version.

I first held one in my hands in 1945 by which time centimetric radar had been installed in RAF Catalina and Sunderland flying boats on convoy-escort duties in the Battle of the Atlantic. By 1945 German submarine crews were on suicide missions like kamikazi pilots, only 1 U-boat in 10 returned to base.

There are more than 100,000 merchant ship and U-boat crew-members sharing Davy Jones locker at the silent bottom of the North Atlantic Ocean. Thus was the ferocity of the war.

Once having detected a centimetric radar beam, and being accurately located themselves, submarine commanders preferred to remain on the

surface, uncover the guns, and fight it out, day or night.

During most of the war there had been little effect on German industrial production by RAF raids. Many bombs fell on open fields and sometimes killed cattle. But by 1944 RAF navigatigators had maps of rivers and cities laid before them. More than a 1000 heavy bombers, Lancasters, could be put into the air, night after night.

With radar they couldn't miss whole cities and individual districts. Nevertheless on one occasion more than 100 bombers, complete with crews, failed to return to base. Such occurrences greatly exceeded the capacity of factories to produce them and to train aircrews.

During the last 12 months of the war, radar equipped RAF bombers killed more German civilians than died in the concentration camps. Hiroshima and Nagasaki, which came shortly after, were just chicken feed. Air Marshal "Bomber" Harris was never knighted for services rendered.

The main beneficiaries of R & B's invention of the cavity magnetron, done amid the high-explosives and incendiaries falling on Birmingam, have been the Japanese and other Far Eastern peoples who have manufactured many millions of cheap, reliable, microwave ovens.

And of course the many millions of people like you and I who benefit from daily hot meals. I detest barbiques.

There was held in the Kensington, London, Science Museum, the original prototype of the cavity magnetron without its magnet. It was in a securely locked mahogany and glass case and looked, as I recollect, like a small dirty can of baked beans with things sticking out of it. It may still be there.

Makes a change from so-called SWR meters.

Reg, G4FGQ.

Ah Rich!, Yet again you deliberately distort my meaning in your
amusing game of 0ne-Upmanship.

For the benefit of lurkers, there's a great difference between meters
which purport to measure SWR at HF, but do no such thing and tell
lies, and probes inserted in waveguides at 3 GHz which tell the truth.

A properly guyed (2 sets of 3) 50 ft. Rohn 25 in a
minimum recommended configuration will support 10.5
sq. ft. of antenna at 70 mph or 5 sq. ft. at 110 mph
according to my Rohn drawings.

My favorite was a short story years ago called "All the names of God". Seems a group of monks in Tibet or some other eastern place were writing all the possible perturbations of their alphabet.

Having completed the task the universe would end as mans purpose had been fulfilled. At the rate they were going the task would be completed in about another 400,000 years or so... That was until an enterprising computer salesman showed them that with a sufficiently large order from his company, the task could be finished in 3 weeks.

As the end of the run came near, the salesman decided to get out of Dodge, as he did not want to deal with a group of pissed off monks when the universe didn't end. Besides he had a hell of a commision to spend!

The last line was a classic "As he looked out the window of the airplane, silently, one by one, the stars were going out".

Jews do not casually write any Name of God. This practice does not come from the commandment not to take the Lord's Name in vain, as many suppose. In Jewish thought, that commandment refers solely to oath-taking, and is a prohibition against swearing by God's Name falsely or frivolously (the word normally translated as "in vain" literally means "for falsehood").

Judaism does not prohibit writing the Name of God per se; it prohibits only erasing or defacing a Name of God. However, observant Jews avoid writing any Name of God casually because of the risk that the written Name might later be defaced, obliterated or destroyed accidentally or by one who does not know better.

The commandment not to erase or deface the name of God comes from Deut. 12:3. In that passage, the people are commanded that when they take over the promised land, they should destroy all things related to the idolatrous religions of that region, and should utterly destroy the names of the local deities. Immediately afterwards, we are commanded not to do the same to our God. From this, the rabbis inferred that we are commanded not to destroy any holy thing, and not to erase or deface a Name of God.

It is worth noting that this prohibition against erasing or defacing Names of God applies only to Names that are written in some kind of permanent form, and recent rabbinical decisions have held that writing on a computer is not a permanent form, thus it is not a violation to type God's Name into a computer and then backspace over it or cut and paste it, or copy and delete files with God's Name in them. However, once you print the document out, it becomes a permanent form. That is why observant Jews avoid writing a Name of God on web sites like this one or in BBS messages: because there is a risk that someone else will print it out and deface it.

Normally, we avoid writing the Name by substituting letters or syllables, for example, writing "G-d" instead of "God." In addition, the number 15, which would ordinarily be written in Hebrew as Yod-Heh (10-5), is normally written as Tet-Vav (9-6), because Yod-Heh is a Name. See Hebrew Alphabet for more information about using letters as numerals

Ah Reggie,

Yet again, you deliberately distort my meaning in your amusing game of
One-Downmanship.

For the benefit of lurkers, there's absolutely no difference between
meters which purport to measure SWR at any frequency. You are simply
fumbling around with one of your conceits, a troll in the lingua
franca of the Internet.

What you now describe was a flicker in time between bombs and crashing
glass that was quickly discarded as an awkward technique when RADAR
went into production. Such troglodyte methods were long gone before
you even wrapped your mitts around a magnetron.

If we pursue this with your absurd reductionist habit of arguing blind
absolutes in place of practical reality (something Lord Kelvinator
would sneer at as a foppish mannerism); then what you describe as
"probes" are measuring nothing about SWR but are doing what any probe
could accomplish: measuring a common unit of voltage, or current (and
only by inference of the actual through rectification and filtering).
The SWR only arrives by a second (or significantly more than two)
reading, and then FURTHER only after various calculations. Even then,

barring calculations (something no one does except squinty-eyed scientists and trolls), those same METERs employed were marked in SWR. Imagine, within very few months of RADAR emerging from the lab, SWR METERs ruled the production line, and the field kit. And to be sure, did they measure SWR? As much as any instrument and to your fulminating frustration, to no obvious difference that would be observed by Maxwell's demon (or Schrodinger's cat) craftily turned to this mischievously scientific validation.

SWR arrived in its full glory of attention with RADAR. They were born simultaneously and absolutely no one gave a fig before on this topic. Further, it taught a generation of engineers the importance of matching production designs (which had been long inbred into the AC power production community - simply a rediscovery of a "truth" that had never been lost). This was probably because the consequence of SWR is so dramatic in the 100s of KW, when it occurs in the locality of the workbench in a system as small as the span of your arms. Even the Old Wives notice it if they, in error, try to microwave a product wrapped in a crumpled foil such as butter is wrapped. Their startled reaction evokes an immediate response, just as my post caused your knee to jerk reflexively beneath your apron.

Hello Walt:

Great story! I printed the story out and passed it around at the local coffee shop yesterday. A collection of distinguished radio enthusiasts. Everyone liked it. I think now some are building loop antennas.

I just saw a story on Amelia Airheart on the History channel I think, it showed a DF Loop Antenna being installed on top the fusalog of their Lockheed Electra Aircraft. The Training secession for the DF Equipment turned into a photo shoot instead of a hands on training session. According to the reporter.

Great story.

Id bet there would be a market for a book of great stories like this one and the one on the Beverage antenna. Please send more.

Jay in the Mojave

Sorry, I don't see any difference between making voltage measurements
with a directional coupler and calculating SWR through meter calibration
and making voltage measurements on a slotted line and calculating SWR
with a calculator or pencil and paper.

Best I can tell is you are saying there is no such thing as a SWR meter.

That's like saying there is no such thing as an airspeed meter in an
airplane; the meter really measures air impact pressure.

If that is your point, so what?

It's quite possible, at this stage of the art, for a female to have a
virgin birth. Even a clone of herself.

A male's sperm is unecessary and is redundent.

In the near future it may need male doctors to do what is necessary.
When females can organise things the situation will slightly change.
Males will be entire redundent except for recreational purposes. They
will then fade away into history.

But all this will not solve the problem of the illegal occupation of
Iraq.

Reg.

Ah Reggie,

As Dr. Johnson would paraphrase himself "claims of illiteracy is the
last refuge of the troll." [Not to deny that you are in plenty of
company - but you would shrug off that association.]

This is notable in that you assert:
>about what can only be a trivial matter
which, of course, means you understood enough not to be able to deny
Lord Kelvinator harrumphing at your feigned attitude. It is an ill
fitted cloak.

>of your chosen ideas of gamesmanship.

This is the truly amusing part, you deliberately raised two topics
(nothing had to be said about SWR meters, certainly - that injection
is your trademark invitation), and you had two respondents answering
to each of them. Even the sewer rats of Rio could see that you
considered the more interesting topic as the one that you have now
three times pursued. Such are the games being played, bucko! ;-)

C'mon, if I hadn't responded you would have been sorely disappointed
and would have had to sneer at David as an american suck-up trying to
soothe an olde codger. You need a lightning rod to keep your current
flowing and your response is the thanks I get.

You're welcome, Old Son!

Greetings!

If you liked that bit, and if you ever studied Latin, this bit may
interest you:

--

CENTURION:
What's this, then? 'Romanes Eunt Domus'? 'People called Romans they go
the house'?

BRIAN (terrified, having just been caught writing graffiti on the Roman
palace wall):
It-- it says, 'Romans, go home'.

CENTURION (puzzled):
No, it doesn't. What's Latin for 'Roman'? Come on!

BRIAN:
Aah!

CENTURION (grabs Brian, holds him in a headlock):
Come on!

BRIAN:
'R-- Romanus'?

CENTURION:
Goes like...?

BRIAN:
'Annus'?

CENTURION:
Vocative plural of 'annus' is...?

BRIAN:
Eh. 'Anni'?

CENTURION:
'Romani'. 'Eunt'? What is 'eunt'?

BRIAN:
'Go'. Let--

CENTURION (twists Brian's arm):
Conjugate the verb 'to go'!

BRIAN:
Uh. 'Ire'. Uh, 'eo'. 'Is'. 'It'. 'Imus'. 'Itis'. 'Eunt'.

CENTURION:
So 'eunt' is...?

BRIAN:
Ah, huh, third person plural, uh, present indicative. Uh, 'they go'.

CENTURION:
But 'Romans, go home' is an order, so you must use the...?

BRIAN:
The... imperative!

CENTURION:
Which is...?

BRIAN:
Umm! Oh. Oh. Um, 'i'. 'I'!

CENTURION (draws short sword, holds to Brian's throat):
How many Romans!?

BRIAN:
Ah! 'I'-- Plural. Plural. 'Ite'. 'Ite'.

CENTURION:
'Ite'.

BRIAN:
Ah. Eh.

CENTURION:
'Domus'?

BRIAN:
Eh.

CENTURION:
Nominative?

BRIAN:
Oh.

CENTURION (continuing to threaten):
'Go home'? This is motion towards. Isn't it, boy?

BRIAN:
Ah. Ah, dative, sir! Ahh! No, not dative! Not the dative, sir! No! Ah!
Oh, the... accusative! Accusative! Ah! 'Domum', sir! 'Ad domum'! Ah!
Oooh! Ah!

CENTURION:
Except that 'domus' takes the...?

BRIAN:
The locative, sir!

CENTURION:
Which is...?!

BRIAN:
'Domum'.

CENTURION:
'Domum'.

BRIAN:
Aaah! Ah.

CENTURION:
'Um'. Understand?

BRIAN:
Yes, sir.

CENTURION:
Now, write it out a hundred times.

BRIAN:
Yes, sir. Thank you, sir. Hail Caesar, sir.

CENTURION:
Hail Caesar. If it's not done by sunrise, I'll cut your balls off.

Or maybe you prefer this one:

--

REG:
And what have they ever given us in return?!

XERXES:
The aqueduct?

REG:
What?

XERXES:
The aqueduct.

REG:
Oh. Yeah, yeah. They did give us that. Uh, that's true. Yeah.

COMMANDO #3:
And the sanitation.

LORETTA:
Oh, yeah, the sanitation, Reg. Remember what the city used to be like?

REG:
Yeah. All right. I'll grant you the aqueduct and the sanitation are two things that the Romans have done.

MATTHIAS:
And the roads.

REG:
Well, yeah. Obviously the roads. I mean, the roads go without saying, don't they? But apart from the sanitation, the aqueduct, and the roads--

COMMANDO:
Irrigation.

XERXES:
Medicine.

COMMANDOS:
Huh? Heh? Huh...

COMMANDO #2:
Education.

COMMANDOS:
Ohh...

REG:
Yeah, yeah. All right. Fair enough.

COMMANDO #1:
And the wine.

COMMANDOS:
Oh, yes. Yeah...

FRANCIS:
Yeah. Yeah, that's something we'd really miss, Reg, if the Romans left. Huh.

COMMANDO:
Public baths.

LORETTA:
And it's safe to walk in the streets at night now, Reg.

FRANCIS:
Yeah, they certainly know how to keep order. Let's face it. They're the only ones who could in a place like this.

COMMANDOS:
Hehh, heh. Heh heh heh heh heh heh heh.

REG:
All right, but apart from the sanitation, the medicine, education, wine, public order, irrigation, roads, a fresh water system, and public health, what have the Romans ever done for us?

XERXES:
Brought peace.

REG:
Oh. Peace? Shut up!

If we're one nation "under god", which god is it?

This is what Michael Newdow should have asked the Supreme Court last
year. Too bad the court weaseled their way out of a ruling based on
the child custody issue.

First of all, atheism is non-belief in deities. That's it. Anything else
you're adding to this concept is your own projection.
Second, you're equivocating and word-playing on the term "belief". What
beliefs are we talking about in atheism? Atheists don't believe in gods
- a lack of belief is not belief any more than baldness is a hair color.
So, then, what beliefs? When you define this I'll "counter the argument"

>>>I do not deny that both are fallible, however, history demonstrates
>>>that the religious, despite their failures, have improved the human
>>>condition immeasurably where atheists have been only a blight upon
>>>civilization.
>>
>>??? You have got to be kidding? What has religion possibly done for
>>anyone except provided false hope while stealing their money?
>
> Law itself is derived directly from religious thought.

Sometimes is, sometimes isn't. In the primitive tribal societies it was
much simpler to rule lawless people if you told them some god passed a
certain law and it just so happens that you have a direct communication
line with that god, so that you can interpret it. This is how religions
got born, and by a curious coincidence they all demanded money from
their followers.
Now, show how, for example, the American legal system is derived from
religion. Point out the law that makes it illegal to "covet one's ass"
or to eat shellfish or to wear clothes made from two different fabrics.

> If there were no belief system, there could be no law.

??? Look, just pulling statements out of your ass does not make them
believable. If you want to convince people, you have to present
arguments in a coherent way.

What is so difficult about law anyway? Does it really take a genius to figure out that murder, rape, slavery, genocide and theft are detrimental to a society? We need some book written by ancient goat-herders to tell us what laws are supposed to be? Besides, where, for example, does the Bible say that slavery is wrong? Oh, that's right, it doesn't - as a matter of fact, it explicitly condones it. It also condones genocide, rape, infanticide and all sorts of other behavior that nowadays is considered uncivilized (albeit only when perpetrated by the God's chosen people against infidels). Strangely enough, there is no mention of abortion in the Bible whatsoever, while one of the two wildly different versions of the Ten Commandments deals with God's humongous vanity.

> Dictatorships have no law, that's what makes them so awful.

??? You're not serious, are you?

>>Stifling science (from Galileo to stem cells), witch burning, condoning
>>slavery, religious genocide on unprecedented scale, eradicating whole

This is false dichotomy. Also, as I said before, atheism is simply non-belief in gods. It does not prescribe any morals, ethics or behavior. Furthermore, if you claim that our morals are based on your scriptures, and if I then go through that "holy" book and find a contradictory example then it should be obvious that your argument falls apart. So if your Bible explicitly condones rape and slavery, how do you reconcile this with your religion-derived morals, other than through cognitive dissonance?

According to you, all atheists should be immoral by definition. It follows that prisons should be overflowing with them. Yet, strangely enough, in American prisons, Christians are over-represented, while atheists (along with Jews and Muslims) are under-represented.

Hmm, do I smell a true Scotsman fallacy coming up?

Most convicts get "religion" because it looks good for the parole board.

The reason Jews are under represented is the high value placed on education by the Jewish culture. A lesson lost on the ghetto dwellers in spite of the fact the early civil rights fight was for an equal education.

As long as niggers equate education with "acting white", they will enslave themselves far more effectively that any plantation Massa of pre War of Northern Agression times.

Once a group learns education opens the doors of opportunity, they are truly free.

Your desperate grasping at straws to support atheism indicates to me, a crying out on your part for someone to lead you to the path of understanding. I shall pray for you my friend.

Even if you do not believe in God, he believes in you!

1035. Hams of FCC's RID Aid Allied Effort in WW2

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-24 23:22:05 UTC
From: Walter Maxwell <walt@w2du.com>
Message-ID: <1gnbj11s90aa1jc5j5cbrgt5i2e00o7k73@4ax.com>
Source record: 70132

I'm aware that this post is off-topic, except that it is the basis for my two previous posts that were on topic to antennas. I believe it is time to reexamine the contributions hams and commercial radio ops made to the WW2 effort as they were the operating personnel of the FCC's Radio Intelligence Division. This is their story.

With the War already raging in Europe in 1939, people at the State Department knew they were missing vital war intelligence being exchanged by radio, especially that going between Germany and South America. They queried the FCC Field Division in early 1940 about monitoring to intercept the information. The Field Division operated the original primary monitoring stations, performing regulatory and enforcement duties. However, at that time the Field Division personnel had their hands full just monitoring domestic operations, and had no time for intelligence monitoring.

Congress was alerted to the need for additional personnel and equipment for the FCC to monitor intelligence, and it approved funds for establishing a new section, the National Defense Operating section, NDO. The NDO began operations September 3, 1940, and was later upgraded to a division, becoming the Radio Intelligence Division, RID. To head the NDO, the late George E. Sterling (W1AE/W3DF) was elevated from Ass't Chief Engineer, FCC, to Chief, NDO Section, and later to Chief, RID. To obtain personnel for the new section he instructed one of his assistants, the late Harriette Koster, to search through the file cards containing the information on licensed amateur and commercial operators. She selected more than 500 operators from the file cards, and over T.J. Slowie's signature, she sent telegrams to those selected, offering them positions of Radio Operator, Ass't Monitoring Officer, and Monitoring Officer. The entire personnel for the new NDO Section, including myself, were obtained from response to those telegrams. (Harrriette later became my wife, and mother of my four children, W2WM, WB4GNR, K4JRM, and KC4UBZ (Sue's license now expired). The Congressional funding also supported building many new secondary monitoring stations throughout the country, each equipped with Hallicrafters SX-28 and S-27 receivers, and Adcock (sky-wave) direction finders. In addition, Hudson automobiles equipped with the receivers and a loop direction finder were a part of each secondary station, used for mobile close-in surveillance.

Immediately following Pearl Harbor, December 7, 1941, the FCC RID mobilized a group from both primary and secondary monitoring stations to go to the Hawaiian Islands to set up eight new secondary stations, one each on Oahu, Molokai, Kauai, Maui, and Lanai, and three on the big island of Hawaii. NDO Chief Sterling accompanied the group, of which I was a member from the primary station at Allegan, Michigan.

Extensive 24/7 mobile monitoring around the shoreline of all the islands was pursued, with the intention of finding clandestine radio operation between local Japanese loyal to Japan and Jap submarines cruising off shore. No such operations were found to occur, and no Hawaiians of Japanese descent were found to be disloyal to the U.S. During my stay on the Islands I worked at stations on

Oahu, Kauai, Molokai and Hawaii.
With Adcock direction finders at all eight secondary stations, plus the one at the primary station in Honolulu, the FCC saved the lives of thousands of military personnel and more than 600 military aircraft flying the Pacific between the Mainland and the Islands during WW2, after becoming lost due to errors in navigation with limited fuel supply. Details on how this task was performed, and how the Beverage antenna was used to receive broadcasts from JOAK Tokyo, were the subjects of my two previous posts.
Within the next few months I'll be relating some of the 'real intelligence' work involving RID operations that had a significant effect on shortening WW2.

1037. Ladder Line and Interference from Metal Objects

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-25 00:23:58 UTC
From: Rockinghorse Winner <rockinghorse@anonymous.to>
Message-ID: <y6mZe.160$Aw.2236@typhoon.sonic.net>
Source record: 70134

Up until now I have avoided considering wire antennas fed with ladder line like a full wave loop or Zepp, because I have metal rain gutters and windowframes, which the line would inevitably have to contend with. Is this a big issue? What kind of an effect do metal objects have on ladder line, and is this prohibitive to putting one up? Should I stick with coax?

Thank you.

It will work, but you have to treat the roof as a psuedo
mobile setup, as it's not resonant. Well... Unless you
get lucky.
I'd just ohm out the roof and see if it's connected before
I started trying to bond it together.
The performance is semi iffy...
In general, radials that are resonant would be better, but
that assumes there are enough of them for a given height.
It's quite possible some bands may be fairly poor, if the
roof shows a high impedance. IE: much like trying to
use 1/2 wave long radials elevated...

It is generally not a problem. You can pass a ladder line
directly across a metal frame, and usually you will notice
nothing. Try to keep the lines at right angles to the metal
frame. Passing metal at right angles, for short distances
is rarely a problem. Running lines along side metal can be.

Message-ID: <dh56e0ndu1@nwrdmz02.dmz.ncs.ea.ibs-infra.bt.com>
Source record: 70151

Jim,

To measure SWR on the line it is necessary to place the SWR meter at the antenna end of the line. Even then it gives the correct answer only when the line impedance is 50 ohms.

But the SWR meter is always placed immediately adjacent to the transmitter. Whatever the meter indicates it is not SWR because there is no line on which to measure it. The meter is telling lies.

The meter indicates only whether or not the transmitter is loaded with a resistance of 50 ohms. Which is ALL you want to know. It tells you nothing more and nothing less.

This is, of course, a very valuable function of the instrument. But it is NOT behaving as an SWR meter. Its name should be changed to Transmitter Loading Indicator (TLI).

To use the name "SWR meter" and to imagine it is actually measuring an SWR is seriously misleading and is a source of confusion about what is really going on.

It is why there are perpetual arguments and misunderstandings about SWR, tuners and related matters on this newsgroup and in every other place.

Change the name to TLI, which is what it really does. Novices will not be lead astray, clear thinking will prevail, false ideas will not take root to remain embedded for the remainder of one's radio career.

Air pressure indicators instead of airspeedometers are OK because air pressure actually exists.

SWR meters are NOT OK because there is no line for SWR to exist on. (At least not where the meter is imagined or supposed to measure it.)

Makes a change from cavity magnetrons.

Reg.

Your sheet is showing, Fred. It's hard for rational beings to
believe in undemonstrable phantasms, but even believing, it's even
harder for any rational being to see how anyone could worship
a mass murderer, as God has proven himself to be over the years, and
still be moral. Morality transcends Christianity because truly
moral people know that belief does not justify the committing of
atrocities, a simple fact lost on most Christians over the millennia.
73,
Tom Donaly, KA6RUH

42' high then 6' of mast pipe for a total of 48'
no guys.
It is anchored with 1yd cube concrete and mounted to a house bracket
9' from bottom.

Antennas at that time where a dual band vertical 7' tall and a discone
mounted on a homemade side arm and a hf dipole.

It survived all the 2004 Hurricanes here in Daytona Beach FL with
known winds of 100 mph.

Granted, as I install more antennas (couple of yagi's and rotor) I
will want to add a set of guy's.

I'd like to say thanks to all who responded to my original question.
There have been a variety of answers.

The only answers I feel might be wrong are those where there is a
reactive component. Surely, this can be removed by lengthening the
antenna by the appropriate amount - but as it is already infinite, this
might be difficult.

Anyway, all very interesting.
Cheers,
Ian.

My installation is as follows: 1) 600 ohm open wire line [tuned of course!] from the antenna to a protected [from WX] area under the sun porch. There I simply connected 450 ohm ladder line to the 600 ohm line for the run into the house. [450 ohm line has increased losses in bad WX]. As mentioned in another response, I run the 450 ohm line at right angles over metal structures. I keep the line a least 6 inches from pipes, heating vents etc and twist the line one twist every three [+/-] feet.

I run 1 KW 80 through 20 meters with NO interference or RFI in the shack. This computer is located 3 feet from the amplifier and has no adverse effects from the amplifier. BTW, my station is grounded [earthed] IAW electrical code.

There are a lot of us out here who share your confidence in your
tower.

I am still using a crank up mast that I purchased in 1979(?). The
mechanics of this thing are more related to a sailboat than a
mountain. I count on it moving when the wind blows to "unload".

It is currently installed without guys and has a Cushcraft A3S on it
so it spends most of its time retracted..

I'm pleased that the history of radio in WW2 is acceptable on this news group. The three threads I've posted so far are from memory, and at the moment that's about all there is.
However, I have files describing many real intelligence transmissions involving historic situations that for the most part went unheralded. These files are in my library at my home in DeLand, Florida. I'm now at my summer home in my home town of Mt. Pleasant, Michigan, but we return to FL Nov 1. I'll dig out some of the files when we return.
Thanks again for the interest. When I posted the first one I thought I might be voted off the island.

for your first attempt at an antenna a kit would probably be best.

something like this may be what you want
http://support.radioshack.com/support_tutorials/communications/swave-4.htm

the ARRL antenna handbook is one of the best and most respected sources on
how to build antennas.

Currently, using the receiver alone with its build in antenna I can listen to the same broadcasts as attaching the wind up antenna into it. Perhaps it improves a wee bit reception, but it's not always noticeable.

Even I'm starting to use the build in antenna with only its first section extracted and placed in a vertical position. Of course, I suffer from fadding and, sometimes, background noise but the wind up antenna doesn't really improve it.

Therefore, will one of those kits help the receiver boosting reception?

Thank you!

1074. Antenna for Danish Radio 1062 MHz

Newsgroup: rec.radio.amateur.antenna

From: Sonnich Jensen <sonnich@NOSPAMhot.ee>
Message-ID: <4337050e$1_1@news.estpak.ee>
Source record: 70171

Hi all!

I have 2 problems:

I'd to listen to Danish Radio P5, on 1062 Medium wawe.
(http://www.dr.dk/omdr/article.asp?aid=532 og
http://www.dr.dk/pubs/nyheder/html/programmer/kortboelge#p5)

My problem is that my raido (tuner) at home must stand on the side, so the ferrit antenna is horizontal. Placing it normally, so it is vertical (and the radio too) it will not get anything. I can connect an antenna.
I have 2 tuners, both have the problem - one old JVC T-10XL (excellent!) and Philips FT772 (digital). The philips doed not have a ferrit antenna, but a large coil somehow. Still, placing it on the side makes it work.

In my car it works well too, but when the engine is running, it create so much noise, that I cannot hear anything but the engine (the radio "ticks", it must create a signal, or come by the power). It is possible to listen too, but hard. How can I avoid this noise?
Better antenna? Engine problems? Power problems?
The alarm causes the same :-) When the LED is flashing, it makes so much noise, that it is not possible to use the radio (with medium wave)

I am listing to all yuor ideas.

PS: send me CC copy, as the neti.ee server does not always get the answers :-)

A college professor, an avowed atheist and active in the ACLU, was teaching his class. He shocked several of his students when he flatly stated that for once and for all he was going to prove there was no God. Addressing the ceiling he shouted: "GOD, if you are real, then I want you to knock me off this platform. I'll give you exactly 15 minutes!!!!!"

The lecture room fell silent. You could hear a pin drop. Ten minutes went by. "I'm waiting God, if you're real knock me off this platform!!!!"

Again after 5 minutes, the professor taunted God saying, "Here I am, God!!! I'm still waiting!!!" His count down got down to the last couple of minutes when a Ranger, just released from the Army after serving in Afghanistan and Iraq and newly registered in the class, walked up to the Professor.

The Ranger hit him full force in the face, and sent the Professor tumbling from his lofty platform.

The Professor was out cold!! The students were stunned and shocked. They began to babble in confusion. The Ranger nonchalantly took his seat in the front row and sat silent. The class looked at him and fell silent waiting.

Eventually, the professor came to and was noticeably shaken. He looked at the Ranger in the front row.

When the professor regained his senses and could speak he asked: "What the hell is the matter with you?! Why did you do that?" "God was really busy protecting America's soldiers, who are protecting your right to say stupid things and act like a jerk !!! So he sent me!!"

an outside antenna generally works better then an inside antenna.

you may need a good ground connection to make the antenna work in an optimal
fashon.

Some lengths work better than others, depending on band. See the web
site, http://www.qsl.net/w5dxp and look at the "tunerless" all band
antenna fed w/ladderline.

Make it as long as you can, as high as you can. I wouldn't worry too
much about length. Keep it away from powerlines, if possible, where
you might pick up noise.

Places like Lowes Home Improvement and Home Depot sell a 500 foot roll
of wire for about $30. Copper, insulated or uninsulated, 14 or 12
guage, is fine.

Radio Shack sells a long wire antenna kit for shortwave listening;
about $10 or less.

Some like to get into long wire "baluns" or coax feeds, but a simple
piece of wire coming in your window, to your receiver, will do about
as well as anything. Start with that -- get fancy later.

It is a tad more than that, Fred.

One of the things that causes me to question the astuteness of so many Republicans is that they steadfastly refuse to take any responsibility for anything. Ever.

They are in power now. They hold the House, the Senate, and the White House. They quite simply ARE responsible by default.

Unfortunately, so many of them appear to be in the finger pointing mode, which is what they have done for so many years.

At some point, it looks like all they can do is point fingers, not actually solve problems.

If after being in just about complete power for the last 6 years, and only out of power in the presidency for 8 of the last seemingly gazillion years, how can this be?

If by this time they haven't reined in the Democreeps, Demacraps, Leeberuls, bleeding hearts, class warfarists, soccer moms, and even us middle of the road "Dead Skunks", who are blamed for every problem on the face of the earth, then what?

Can't have it both ways - unless those people who are not in power are somehow more powerful than the people who are in power. At some point people aren't' going to believe the finger pointing any more.

> I know for a fact the Red Cross was told that if they were to feed the

When I was a young feller, I recall many stories in bible class about good Christians who defied the law to do the right thing. I thrilled to stories about Christians who defied the Nazi's to protect Jewish people who would be otherwise killed, about brave Christians who managed to survive in Communist China. Lots of wonderful inspirational stories about religious conviction and character.

My how Christianity has changed! Must be a strong religion that won't go against an HOA.

1087. Re: Hams of FCC's RID Aid Allied Effort in WW2

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-26 01:37:15 UTC
From: "J. Teske" <jdteske@comcast.net>
Message-ID: <qqhej1pn8oult0a10i8npli4fadridbjgb@4ax.com>
Source record: 70084

The primary responsibility for monitoring for foreign intelligence purposes during WW II, of course belonged to the military (as indeed it does today - NSA, the US cryptologic authority, from which I am a retiree, is still part of the Department of Defense). During WW II and before, the predecessors of NSA also had a number of monitoring stations around the world and the the US Coastal areas and even on the roof of the Navy Department in the "Temporary" WW I buildings on the Mall. [Temporary indeed, they weren't torn down until the US Bicentennial in 1976. They were located just about where the Vietnam Memorial is today in Washington although they extended for blocks up Constitution Avenue.] The first of these intercept operators called themselves "The On the Roof Gang" and that actually became the name of their alumni association when they had post war reunions. Many of my first supervisors in my early days at NSA were part of this group. They were doing intercept primarily for collecting enciphered messages for codebreaking and during the war that was an Army and Navy responsibility. That history is pretty well documented by the History Department at NSA and the National Cryptologic Museum at Ft. Meade, MD (Open to the public BTW) and by numerous historians. The literature about the Purple Code,the codebreaking which permitted victory at Midway, The Ultra Secret and the like can fill whole bookshelves. The story of some of these less well known contributors really does have to be told. As a retired cryptologist, I am intimately familiar with the military contributions and those of the Brits and even the Poles in Exile (Polish mathmeticians were the first to get into the German ENIGMA systems and they managed to get to Britain before they could be captured by the Germans). This FCC Radio Intelligence Division story is certain less well known (read: I hadn't heard about it before) and deserves to be known. Some of their lifesaving missions, for example are the sort of thing the military intelligence types didn't do except by serendipity, nor would they have monitored domestic broadcasting by the enemy. The military ops also would not have done any law enforcement or domestic mission.[The Posse Comitatus Act from the Indian Fighting days on the 1870's and still in force today prohibits the military (as opposed to the National Guard who technically fall under the command of state governors) from law enforcement and domestic intelligence missions.

I do remember Alegan, Michigan (and also Grand Island, NE) facilities because I got a violation notice in 1956, my first year as a ham (for the same incident) from each of these two stations for 2nd Harmonics from my 80 meter Novice band transmissions. I can't begin to tell you how scared I was as a 13 year old to have a "Federal Case" against me. 35 years later, I had a "big government meeting" with the Chief of

Staff of the FCC at FCC HQ in Washington. By then, I was a DOD/NSA executive and he was the highest ranking careerist at the Commission and I told him just how scared I was of the FCC back then. He commented that he wished all their violators took the Commission that seriously. Considering the matter at hand at that meeting (a Defense Department/FCC policy issue) he said that now maybe it was his turn to be afraid of me. :-)

Keep these stories coming. I also think that the historians at the National Cryptologic Museum would be interested in your stories. You can write me back channel on that.

What has this got to do with atheism? I still don't see any faith or
belief in *not* believing that a magic supernatural dude created
everything. Not believing supernatural and paranormal concepts is a
default state. If you want to convince me or anyone else about your
extraordinary claim, you have to provide extraordinary evidence. Simply
saying "it is so because I say it is so" does not cut it.

Governments, much like armies, for all their faults and problems, are a
necessary evil, unless one advocates anarchy as a solution. Religion is
not.

The straw is that there seems to be something in human nature that
needs to believe in a higher power. Myths and religion wouldn't
exist unless they fulfilled some need. One reason that we are more
successful than our ape cousins is that we can control the bullies
in our society. Religion helps to accomplish that control.

> only when the line impedance is 50 ohms.

Well, duh.

Anyone that doesn't know that SWR is with reference to a stated
impedance or that SWR is influenced by the characteristics of a
real transmission line just isn't paying attention.

> But the SWR meter is always placed immediately adjacent to the
> transmitter. Whatever the meter indicates it is not SWR because there
> is no line on which to measure it. The meter is telling lies.

Errr, no, the meter is telling what it sees at the point of measurement.

If the measurer is so opaque that he/she doesn't take line influences
into account, it is hardly the fault of the measuring instrument that
what is reported is not the SWR of the antenna at the specified
impedance.

> The meter indicates only whether or not the transmitter is loaded with
> a resistance of 50 ohms. Which is ALL you want to know. It tells you
> nothing more and nothing less.

Basically true given the stated conditions, and all that is probably
of interest for the average ham.

> This is, of course, a very valuable function of the instrument. But
> it is NOT behaving as an SWR meter. Its name should be changed to
> Transmitter Loading Indicator (TLI).

Uttern nonsense; the instrument is still behaving as a SWR meter but
the user is not applying it per spec and not correcting measurement
error caused by line position.

By this logic we have a lot of names to change. For starters:

PAM has to change the name of their cooking spray to: Teenage looser
get high in a can.

Screwdriver manufacturers have to change the name of their product
to: General prying instrument and paint can lid removal tool.

You may add others.

> To use the name "SWR meter" and to imagine it is actually measuring an
> SWR is seriously misleading and is a source of confusion about what is
> really going on.

Nonsense, the meter is always measuring SWR but the user is obviously
not measuring the SWR that would be seen at the end of the line.

You can't fault the instrument for it's misuse by the ignorant.

What would you call a low impedance voltmeter used by some nimrod
to measure voltage in a high impedance circuit?

> It is why there are perpetual arguments and misunderstandings about
> SWR, tuners and related matters on this newsgroup and in every other
> place.

That is probably true since most people are opaque as to what goes
on on a real transmission line, but not everyone is.

> Change the name to TLI, which is what it really does. Novices will not
> be lead astray, clear thinking will prevail, false ideas will not take
> root to remain embedded for the remainder of one's radio career.

Clear thinking would demand that the influences of a real line on the
observered SWR at an arbitrary point be explained.

> Air pressure indicators instead of airspeedometers are OK because air
> pressure actually exists.

Non sequitur; SWR actually exists. Getting an accurate measurment is
another issue and a matter of education.

> SWR meters are NOT OK because there is no line for SWR to exist on.
> (At least not where the meter is imagined or supposed to measure it.)

Nonsense.

> Makes a change from cavity magnetrons.

More nonsense and not even a sentence.

About the only difference between microwave and HF is that it is a lot
easier to build a line, i.e. waveguide, that approximates a theoretical
ideal lossless transmission line for reasonable distances at microwave
than it is to build lossless coax as commonly used at HF.

All the theory remains the same.

Personally, I have never had any problem with understanding what it is
that a SWR meter displays.

On the contrary, human imagination brings lots of concepts into
existence. Your words, above, are just one example. Your word,
"god", represents a concept that does indeed exist. "Love" is
another concept that exists although I have never seen a drop
of love.

My Rohn 25 is as follows
42' high then 6' of mast pipe for a total of 48'
no guys.
It is anchored with 1yd cube concrete and mounted to a house bracket
9' from bottom.

Antennas at that time where a dual band vertical 7' tall and a discone
mounted on a homemade side arm and a hf dipole.

It survived all the 2004 Hurricanes here in Daytona Beach FL with
known winds of 100 mph.

Granted, as I install more antennas (couple of yagi's and rotor) I
will want to add a set of guy's.

Hi Mike,

Perce was commending me (or so I read the reply to my post, which had
quoted Fred's top post (which makes attribution complex)).

Either way, what is more amusing is the anal-retentive attention given
to forcing the metaphor of the Camel to come out "correctly" by
successive writers and critics (thus proving it is easier to go to
hell through accuracy than get to heaven with style). Of course, none
of this matches the absolutely amateur religious instruction on what
constitutes an atheist - again, the toboggan run to hell paved with
definitions, examples and references reaching back to the dawn of the
crusades as proof.

Style is found in:
"Now I saw in my dream that Christian and Hopeful forsook Mr. By-ends,
and kept their distance before him; but one of them looking back, saw
three men following Mr. By-ends, and behold, as they came up with him,
he made them a very low bow; and they also gave him a compliment. The
men's names were Mr. Hold-the-world, Mr. Money-love, and Mr. Save-all;
men that Mr. By-ends had formerly been acquainted with; for in their
minority they were schoolfellows, and were taught by one Mr.
Gripe-man, a schoolmaster in Love-gain, which is a market town in the
county of Coveting, in the north. This schoolmaster taught them the
art of getting, either by violence, cozenage, flattery, lying, or by
putting on the guise of religion; and these four gentlemen had
attained much of the art of their master, so that they could each of

them have kept such a school themselves.

"Well, when they had, as I said, thus saluted each other, Mr. Money-love said to Mr. By-ends, Who are they upon the road before us? (for Christian and Hopeful were yet within view).

"BY-ENDS. They are a couple of far countrymen, that, after their mode, are going on pilgrimage.

"MONEY-LOVE. Alas! Why did they not stay, that we might have had their good company? for they, and we, and you, Sir, I hope, are all going on pilgrimage.

"BY-ENDS. Why, they, after their headstrong manner, conclude that it is duty to rush on their journey all weathers; and I am for waiting for wind and tide. They are for hazarding all for God at a clap; and I am for taking all advantages to secure my life and estate. They are for holding their notions, though all other men are against them; but I am for religion in what, and so far as the times, and my safety, will bear it. They are for religion when in rags and contempt; but I am for him when he walks in his golden slippers, in the sunshine, and with applause."

Auditions for readings follow this posting.

Not at all, I keep saying, and you refuse to hear it, that I d-o n-o-t
b-e-l-i-e-v-e i-n y-o-u-r g-o-d-s. Any of them.

Once again, absence of belief is not a belief. Let me illustrate:
suppose that someone accuses you of being a witch. He has no evidence,
other than he believes he saw you kill someone's cow with a spell. Now,
you obviously don't "believe that you're not" a witch, do you? It would
seem that his claim needs evidence/proof and you have nothing to believe
in and nothing to prove.
So now you're saying that his belief and your "belief" are somehow similar?

> What you seem to be doing is standing on soap box and claiming that

> religion. Atheism, in other words doesn't exist, it cannot exist in
> any real sense. Rather than I proving that an elephant can't fly, why
> don't you prove that it can?

Why don't you prove that your gods, devils and angels exist first, before engaging in the standard theist shifting of the burden of proof. If you have nothing to show for your gods other than the usual begging the question and other logical fallacies, then I don't have to entertain your hypothesis with any more seriousness than the hypothesis that the Universe was farted out of the Super-Nuclear Donkey's butt yesterday afternoon.

Either way, Matt, you keep spinning the old tired religious nonsense about atheism being just another theism, because that's pretty much the only thing they can say on the matter, other than engaging in the ad hominem about atheists' immorality, that is.

However, none of this would matter one bit and I would care about Christianity as much as I care about some Amazon tribe's river gods, if it weren't for the fact that the religious right affects my life in the profoundly negative way, and the list is getting longer by the day: health research, contraceptives, euthanasia, abortion, education, politics, freedom of expression, "morality" laws, taxes, phony illegal wars, etc.

Americans have almost absolute freedom to practice their religion in their homes and in their churches as they please, but that is never enough for the Christian Taliban, is it? They won't be happy until this country becomes a Christian Saudi Arabia.

I am not arguing that the *concept* of a god does not exist. I am arguing that in the absence of any evidence of the existence of the alleged gods, as well as considering the preponderance of scientific evidence contrary to all known religious scriptures, it is silly to believe in any of them. And why? Because some 5000 year old goat-bugger had too much to drink one day while trying to figure out stuff no one will ever know.

What difference does it make what I "believe"? When it comes to blind faith in the supernatural and paranormal, I believe none of it until it can be scientifically repeated, falsified and explained. Other than that, I believe the Sun will rise tomorrow and I believe in peace and love, and I believe I'll have a beer. But please don't go confusing these three "beliefs" with the belief in the supernatural. This is the equivocation game and it's dishonest.

> Atheism is a logically faulty concept. Being human, you cannot
> possibly know everything.

What difference does this make? I don't know how the Universe began and quite possibly no one will ever know exactly, but does that mean we can simply pull the "answers" out of our asses? I am not playing the god of the gaps game either. That's just stupid.

> What you may think of the unknown is
> entirely up to you, but whatever that may be, will require just as
> much faith as any other religion. Your religion simply has different
> trappings.

[sigh] I suppose it's hopeless.

You keep blindly repeating what your voodoo practitioners told you, and are unwilling to accept that atheists get to define what atheism is - not you. So feel free to believe (no pun) that atheism is religion or that atheists "deny" God, but I am telling you that the only thing that atheism is, is the absence of belief in gods. Period.

And to everyone's relief, this will be my last post. Whoever wants to follow up is free to transfer the discussion to alt.atheism, soc.atheism or talk.atheism.

> Errr, no, the meter is telling what it sees at the point of
measurement.
>
==========

But the meter is not seeing an SWR because an SWR does not exist.

Where is the 50-ohm transmission line on which the SWR is imagined or
supposed to lie?

As you are unable to answer that question, the remainder of your
argument (which, as I say, arises because of the SWR meter misleading
misnomer) falls flat on its face.

You are an intelligent person. I don't doubt you have no problems
with understanding what the so-called SWR meter really indicates. But
you didn't learn this from observations of the SWR meter - as you
already know it tells lies!

Just to reiterate, the so-called SWR meter indicates only whether or
not the load on the transmitter is a resistive 50 ohms. If it is not
50 ohms it will not tell you what it actually is. Not that you need to
know what it actually is because you will readjust your tuner, without
thinking about it, to make it equal to 50 ohms. Which corresponds to
no deflection of the meter needle.

The TLI is a very useful and valuable device. It does not lead
novices and old-wives (who ought to know better) into false ideas, or
cause confusion and misunderstandings within the amateur fraternity.
Professionals dismiss SWR for what it is worth anyway.

Goodby to SWR except on lines where it matters and where it can be
measured. Which, in practice, are very few.

Reg, G4FGQ.

==========

It is unfortunate that Hollywood so long has dominated the world's supposedly desirable standards of human behaviour and described, by countless examples in films, the ficticious and imagined way of life in the USA. But the truth about real life went to pot after Charlie Chaplin and others were expelled from your shores.

Things may be different now that the Japanese wealth and enterprise have taken over Hollywood. But perhaps it is too late. The Internet, not Hollywood, is taking over the dissemination of ideas. Big Brother Rules!

They who own and control the means of communication will rule the Earth.

Makes a change from so-called SWR meters.

Reg, G4FGQ.

SNIPPED in the interest of saving meaningless reading time.

Mike, It seems that you do NOT understand the Federalist, philosophic
and political principle of Subsidiarity.

In a Federalist system, such as the USA, responsibility begins at the
LOWEST level of government and rises as the problems exceed local
capability. Then local government [eg. city] requests assistance from
the next level of government [eg county]. County, after they cannot
assist, requests assistance from state. State then requests assistance
from regional or Federal government. It does take time for things to rise.

In you view the national government, GW Bush, is 100% responsible if a
city fence falls into your backyard. It doesn't work that way.

Also, you seem to forget that the MOST POWERFUL person in the National
Government is NOT the President. It's not even in the Executive Branch.
Do you know who it is? Think about it!

If an atheist believes only in things that can be proven using
the scientific method, he is the *exact opposite* of a religious
person who substitutes blind faith for scientific inquiry.

> Atheism, in other words doesn't exist, it cannot exist in
> any real sense.

This is known in scientific logic as begging the question. The
onus of proof is upon you to first prove that a supreme supernatural
being exists. Only after you accomplish that scientific feat of
classic logic would you be in a position to discuss the implications.

> Rather than I proving that an elephant can't fly, why
> don't you prove that it can?

The onus of proof is upon the person who asserts the positive
premise which is: "God exists." Until you prove your premise, all
of your arguments are easily recognized as logical diversions.
Therefore all of your statements must be prefaced with:
"If and only if my particular God exists, ...".

If the existence of God were ever proven beyond a reasonable doubt
and atheists continued to disbelieve, then atheism would become a
religion, but not before.

> You have made no case for atheism.

Not that I'm an atheist, but here is the case for atheism: The
existence of even one of the following as a supernatural being
has never been proven.

Allah, Aphrodite, Ares, Athena, Apollo, Artemis, Babaluaye,
Bacchus, Baldur, Bast, Bellona, Brahma, Brigid, Ceres, Cupid, Cerridwen,
Demeter, Diana, Dione, Dionysus, Eris, Eos, Eleggua, , El Shaddai,
Elohim, Eshu, Ereshkigal, Frigga, Frey, Freya, Gaea, Lord Genesa, Hades,
Hebe, Hera, Helios, Hel, Hephaestus, Hermes, Hestia, Horus, Ibeji, Ifa,
Inanna, Indra, Ishana, Ishtar, Isis, Janus, Juno, Jehovah, Jove,
Jupiter, Kali, Krishna, Kronos, Korravai, Loki, Lugh, Lord Indra,
Manitou, Mars, Mercury, Minerva, Mercurius, Morrigan, Nahuiquiahuitl,
Nanahuatzin, Nephthys, Neptune, Obatala, Odin, Ogun, Oshosi, Oshun,
Osiris, Oya, Orunmila, Olokun, Olodumare, Pluto, Persephone, Poseidon,
Proserpina, Quetzalcoatl, Ra, Lord Rama, Rhea, Saturn, Set, Selene,
Shango, Lord Siva, Tammuz, Thor, Tir, Tiw, Uranus, Venus, Vesta, Vishnu,
Vesta, Vulcan, Wotan, Yahweh, Yemaya and Zeus

Even the very existence of a supernatural dimension or realm has never
been proven.

Religion is based on blind faith and beliefs in things that cannot be
proven. Atheism is based on an absence of blind faith and beliefs in
things that can be proven beyond a reasonable doubt.

False. Certain characteristics of entangled particles are
completely random and must remain so in order to avoid faster
than light transfer of information, something presently
considered to be impossible. Can your G-d communicate at
faster than light speeds?

> Atheists are no different than the religious, they, as do the
> religious themselves, simply believe in different things.

False. The absence of a belief is the exact opposite of the
existence of a belief. By your logic, the absence of a tree
is exactly the same thing as the presence of a tree. Methinks
you picked the wrong newsgroup to try to flim-flam. Are you
an EH antenna salesman by any chance? :-)

On my system, there's a 50 ohm cable from the transceiver to
the input of the SWR meter and another 50 ohm cable from the
output of the SWR meter to the balun. Each of these cables
forces the ratio of the voltage to current in each of the
traveling waves to a value of 50 ohms. I have an in-line
Autek WM-1 and no tuner.

There are some atheists who say that there is no god, and there are others who say that the existence of any god can neither be proven nor disproved. Either way, those asserting a belief in a god have the burden of proof. It's not up to atheists to prove that a god does not exist. Of course, you are correct when you say that humans cannot possibly know everything, but to accept a concept such as "god" is applying faith without any critical thinking or reason. This is blind faith.

Of course, if you paint with that broad of a stroke, faith can mean
just about anything you want it to mean. To say that atheists have
"faith" in their beliefs or that such beliefs are actually a religion
is flawed. I can assure you that if some winged being flew down out of
the sun and ended all disease, suffering, and hunger, and brought
peace to the world, and if every person in the world called this being
"god" in their own native tongue, I guarantee even the most hardcore
atheist would have faith in that god.

> supposed to lie?

In my personal case, there is 50 Ohm transmission line between the
transceiver and the SWR meter, then a length of line to a coax switch,
then several lines out to antennas.

You seem fixated on haveing some magical length of transmission line
being necessary for a SWR to exist. This is nonsense.

> As you are unable to answer that question, the remainder of your

Babble.

A SWR meter indicates what is. Knowing what the reading really means
is a matter of education, not veracity.

> Just to reiterate, the so-called SWR meter indicates only whether or
> not the load on the transmitter is a resistive 50 ohms. If it is not

With some education and multiple measurements, you can caluclate
the actual impedance if one desires.

What tuner? What makes you believe everyone has a tuner?

> The TLI is a very useful and valuable device. It does not lead

no, the current is going to want to get down to the tower base anyway. and
code requires the base of the tower be grounded. properly grounding the
base of the tower should prevent cracking of the base (if that is even
possible) by spreading the current out around it.

Hi Phil,

What a nervous twitch. Eager to pin it to 100% as more easily
defended? Zen politics.

Reading across the republican spectrum reveals that they are
struggling with his performance far more than the left - and no doubt
given this is the first left-wing fascist administration they've ever
backed.

It won't be many years before the republicans blame Clinton for GW.
You see, that is what works for tying 100% responsibility (or 68%,
minimum passing).

Hi Reg,

Which only proves Jim is correct, in that you reject the facility to do it with a line. My SWR meters do in fact have a 50 Ohm line transiting from the gozinta to the comesouta. Your poor choice of vendor, or poor solution implemented in design is your own problem, not that of the world's.

I see that you still enjoy its mutilated discussion to the obvious neglect of magnetrons. Much better than flogging Kelvinator, I suppose.

Now there's an image, you going nose to nose with him. He'd send you back to lower 6th for missing the bloody obvious.

Perhaps this is a dumb question Reg, but if the transmission line isn't there, how does RF get from the transmitter to the antenna?

Thanks, ac6xg

1141. Free space pathloss calcs and factor K

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-26 17:59:32 UTC
From: Bob Bob <bob3bob3@cox.net>
Message-ID: <5hpl03-3ps.ln1@p400bob.personal.cox.net>
Source record: 70038

Hi all.

No doubt I could get this reading lots and lots of text books. It might however be interesting to air a discussion on it..

Have been reading the free space pathloss formula from the ARRL antenna handbook;

Loss in dB = K + 20logf + 20logD

Where f is the freq in GHz and D is the distance in miles

K is a constant of around 96.6dB

I have known about a "fixed K" loss in an antenna system for ages. It even made mention I think in this NG recently when talking about a passive repeater system. From my own exposure to path modelling (EDX/Pathloss etc) I noted a very high dB loss per distance rate in the first (say) 100 wavelengths when looking at graphs of same. (I wasnt doing the actual job, just providing data to the engineer to compare measured with predicted. Fascinating stuff!)

What I wonder is where roughly does the 96dB odd "come from". More interestingly can it be reduced by any appreciable amount. Is it maybe a antenna to "air" coupling loss, maybe even that a RX antenna cant possibly extract all of the energy from the wave as it goes past. I would appreciate any input on this.

My initial forays (as a young ham) into LOS paths went through the isotropic/point source radiators and looking at the surface area of the covered "sphere" containing all of the radiated power idea. Then the RX antenna "aperture" area was used to calculate the actual received power. Needless to say it never met the actual measured values!

Cheers Bob VK2YQA (in W5)

For interest the K is 36 if the frequency is in MHz and the distance in miles, or 32.5 if the distance is in Km.

Used it for years and it's never far out.

Why do you keep insisting that SWR can only exhist on a 50-ohm
transmission line. There are a multitude of impedances in transmission
lines that are other than 50-ohms. SWR is present on every and any
transmission line that doesn't match the transmission element perfectly.

Actually no one has a tuner. To tune an antenna you must make physical adjustments to the length, location, size, etc. to the antenna. What one has is an impedance matching network. Modern transmitters are set to expect a characteristic impedance of 50-ohms. If the transmission line and antenna system is not 50-ohms you must insert various values of capacitance and inductance so as to make the transmitter think it is looking at 50-ohms. Older, read tube, transmitters, read finals, generally have adjustable inductance and capacitance elements between the output plate/s and the transmission line. Adjusting these does the same thing as using an external transmatch.

If we are going to be picky lets be accurate. Now, having said this if I happen to be wrong on any specific element I welcome correction not scorn.

>NOT on a line which isn't there. QED.

In the strong sense of the definition ("A VSWR meter is a meter which measures, literally, the ratio between the voltage maxima and minima present on a transmission line"), Reg is correct. This can be done with a section of slotted line and a probe, of course, tapped into a section of a transmission line having the same characteristic impedance.

That's not how a typical amateur "SWR" meter works, though - it's not either locating or measuring either the maxima or the minima of either voltage or current on the line. So, the strong, literal, pedantic sense of the term, I agree with Reg that a standard "SWR" meter is not truly measuring SWR, and that he's correct in his objection.

However, I also think he's overstating the case.

An "SWR" meter circuit, in the usual sense (e.g. a Monimatch or similar) can provide an accurate *indirect* measurement of SWR, *if* the conditions under which it is used are appropriate. It measures the currents and voltages flowing through it, and derives (electrically and mathematically) a number which correlates extremely well to what a true SWR measurement on a T-line of specified impedance would say. If you build and calibrate this sort of circuit accurately enough, and then put it in the middle of a section of 50-ohm line (or whatever it's calibrated for), it'll give the same numbers as a true, direct measurement of VSWR on a length of T-line at that point.

Now, it's true (as Reg says) that a Monimatch or similar indirect-measurement meter can give you inaccurate or misleading numbers, if used in an environment other than what it's designed for. If you stick a Monimatch at the output of a transmitter or transmatch, with its output looking into a high-impedance balanced line, then the numbers it displays won't equal the actual VSWR on the line. You might be able to come up with a correction factor / curve for it, though. If you stick it right at the transmitter output, and it reads 1.0:1, then you can be confident that your transmitter is seeing the load that it wants to see... hence Reg's desire to have it renamed as a "TLI".

Seems to me, though, that the same is true of a real "VSWR" measurement system (e.g. a slotted line) if you use it under

inappropriate test conditions. If you take a slotted-line-and-probe measurement device whose internal line is 50 ohms, and stick it in the middle of a 75-ohm line, and measure the VSWR on your slotted line, you'll come up with a number which *does* equal the VSWR in the slotted line but does *not* equal the VSWR on the actual transmission line. Same problem, really.

In that sense, even a "real" VSWR meter isn't a "useful" VSWR meter, if you use it inappropriately.

All that being said: I conclude that there's nothing wrong with calling a Monimatch (or similar) current/voltage measurement circuit a "SWR" meter, as it *will* display correct and accurate numbers for the SWR on the line when used appropriately (within the limits of its calibration, of course). It's up to the user to understand the conditions under which this sort of measurement can be made accurately and usefully... just as it is with every other sort of test instrument I know of.

Reg, I think you're tilting at windmills.

The 50-ohm line on which the SWR is supposed to be measured is between the transmitter and the so-called SWR meter.

If the transmitter is connected directly to the meter, (as it usually is, very often it is inside the transmitter on the front panel) there is no line and no SWR on it which can be measured.

Neverthess, the meter still provides a reading of SWR. Obviously it is telling lies and causes confusion and misunderstanding to novices about what is really happening within their equipment. In fact, just as it has been doing since Joker, Richard Clark, entered the thread.

Some people force themselves to imagine a 1/4-wavelength transmission inside the little box in a vain endeavor to explain how an SWR meter works.

Actually the meter indicates whether or not the transmitter is loaded with 50-ohms - and nothing else. It is an HF resistance bridge to which its circuit reduces.

But, as I say, it is a very useful, almost indispensible instrument. It is a TLI.

What you're saying is that there's a line connecting the transmitter to the meter, but there isn't a line connecting the transmitter to the meter. I'd have difficulty defending such a position.

I don't think the meter really knows what impedance the transmitter is loaded with. As far as I can tell, it only knows how many volts and amps gozinta one port and/or compared with how many volts and amps gozinta the other port.

But I agree that some people read an awful lot into the measurements they make with one of these devices.

> It is an HF resistance bridge to

I have not insisted, not even mentioned, that SWR can exist only on
50-ohm lines.

All I have said, somewhere, is that the usual SWR meter gives the
correct answers only on 50-ohm lines.

No, the SWR being measured is on the load side of the meter.

> If the transmitter is connected directly to the meter, (as it usually
> is, very often it is inside the transmitter on the front panel) there

Bzzzt, wrong answer. SWR is measured on the output side of the meter,
not the input.

That would be inane.

All one need do is realize the meter measures toward the load.

If I connect a 100 Ohm antenna through a 100 Ohm transmission line to
a SWR meter designed for 50 Ohms and then to a transmitter which expects
a 50 Ohm load, does the meter read correctly with respect to the desired
transmitter loading?

Of course it does.

>Of course it does.

Jim, that seems inconsistent with your earlier statemetn "No, the SWR
being measured is on the load side of the meter."

In the example you quoted with a 100 ohm load on a 100 ohm line, were
the line loss low, and the line long enough to be sure to sample a
fully developed voltage maximum and voltage minimum it would be found
that the VSWR was 1:1.

Yet we would expect the "SWR meter designed for 50 Ohms" to which it
is connected (on the load side) to read VSWR=2:1, so is it measuring
the SWR on the load side of the meter as you earlier stated?

Perhaps typical SWR meters are actually sampling current and voltage
on a very short section (almost a point sample) of transmission line
that is part of the instrument, and they are indicating what the
observed SWR would be on an extended line of that type, provided that
attenuation was insignificant, and that the extended line was
sufficiently long to allow full development of the standing wave
pattern.

The inference of what is happening on adjacent line is ours, not the
instruments, as demonstrated by your example above.

Owen

The load side is the side with the load, i.e. the antenna, on it.

> In the example you quoted with a 100 ohm load on a 100 ohm line, were
> the line loss low, and the line long enough to be sure to sample a

Not for a 50 Ohm system, i.e. a transmitter expecting 50 Ohms and a
meter calibrated for a 50 Ohm system.

> Yet we would expect the "SWR meter designed for 50 Ohms" to which it

Yep.

> sufficiently long to allow full development of the standing wave
> pattern.

The SWR that most people care about is that of the antenna.

Usually you have a 50 Ohm transmitter connected to 50 Ohm line, and
then to an antenna you hope is 50 Ohms.

To accurately measure the antenna SWR without any error being introduced
by line losses, you have to put the SWR meter at the end of the line
adjacent to the antenna.

This is usually impractical and we normally put the SWR meter near the
transmitter.

In this case the meter measures the SWR of the entire system, i.e. the
line going from the meter to the antenna and the antenna.

The net practical effect of the line loss for real line and real antennas
is that the observed SWR will indicate a lower value than if the meter
were directly connected to the antenna.

Thanks for your support, Ken, I appreciate knowing my writing is of interest. However, re Prose's call sign, please refer to my earlier thread, "The Correct Polarization Saves Lives....", and my post beneath the original posting, where I showed his call signs correctly.
Incidentally, Prose was a close friend, having worked together both at the Allegan primary station, and in Honolulu. We traveled to Hawaii together in the first group of FCC personnel that arrived there to set up eight new secondary stations. In addition, I was his best man during the wedding to his second wife, and I was also a member of his advisory committee working on WARC 79.

I am sorry Jim, the VSWR is a property of the transmission line and
its termination, and the VSWR on that 100 ohm line with a 100 ohm
termination is 1:1. The VSWR could be *MEASURED* on that line by
sampling the magnitude of the voltage at different points on the line
and it would be found that the magnitude of the voltage was constant,
which means VSWR=1:1.

>
>> Yet we would expect the "SWR meter designed for 50 Ohms" to which it

>Yep.

No, it isn't.

The SWR meter in your example reads 2:1 when the SWR on the 100 ohm
line is 1:1. Your example demonstrates that a typical SWR meter does
not measure, or necessarily indicate the SWR of the (actual)
transmission line on the load side of itself.

I would add "dittos" to that. As the "next" generation after WWII I am a
big fan of that period's history. I wish I had been born in 1923 instead of
'48!

To me, info of this sort is much appreciated since I couldn't experience
that era for myself. Reckon that's why I still listen to Glenn Miller? :)

>What I wonder is where roughly does the 96dB odd "come from". More
>interestingly can it be reduced by any appreciable amount. Is it maybe a
>antenna to "air" coupling loss, maybe even that a RX antenna cant
>possibly extract all of the energy from the wave as it goes past. I
>would appreciate any input on this.

Don't know that particular expression but plug in very low
values for 'f' and 'D' and you come up with something like
Loss(dB) = K(dB) -(~100dB) since the log of numbers less than 1 is
negative.

The formula then is simply of the form -

y = 20log(f) + 20log(D) + C

So when 'f' and 'D' are both equal to 1, the path loss = 96dB
and, when much less than that, it approaches zero.

Cheers - Joe

I've always loved that statement "Live Free or Die". Good for New Hampshire!! I would've done well in New Hampshire!

Like you, I made 2 requirements. 1) No HOA's. and 2) No "heat" pumps!! I know it gets colder in NH, but it CAN get a bit chilly here in Western NC. I won't have cold air coming out of my registers! LOL! And that, of course, is a story for a different thread!

For transmitting purposes you will need to provide a good RF ground
at your tuner. This can be ground radials, good, or a ground rod, not
so good. The ground makes up the other (necessary half) of your long
wire antenna. A 1/4 wave counterpoise wire at the operating frequency
will provide a good? RF ground.
The unbalanced tuner should have the "long wire" connected to the
"hot" or rf output of the tuner, and the ground or common connected to
the RF ground.

Jim says,
> No, the SWR being measured is on the load side of the meter.
==========
Jim,

I have difficulty in telling you this without hurting your feelings. Or perhaps you are just joking and pulling my leg. Try the other one - its got bells on.

I will assume you are not joking. You clearly havn't the foggiest idea of how the so-called SWR meter works. Although you may be in good company - including not a few professional engineers who have picked up old-wives' tales from radio amateurs. And have been led astray by the meter being called something which it isn't.

The meter indicates SWR when placed at the ANTENNA end of the line. It is the antenna which does the terminating. And the meter gives the correct answers only when the line Zo = 50 ohms.

If there is a tuner or matching network in the line then the meter will indicate SWR on the line between the transmitter and the tuner - provided the meter is placed next to the tuner.

When there is no appreciable length of line between transmitter and tuner (as is the very common case) there is no line on which to measure SWR. But the meter will indicate an SWR - and tells lies.

But there's nothing to worry about just because the meter is indicating SWR nonsense. The meter is telling you what you really want to know, its exactly why you placed it there - whether or not the transmitter is loaded with 50 ohms.

Yes, but if the long wire is on the order of a half-wavelength, the
ground becomes a lot less critical.

It becomes less critical in terms of the need to provide the "other
half" of the radiator.

However, if the long wire is roughly a half-wavelength long, its
feedpoint impedance is going to be rather high... possibly higher than
you can match with a typical "unbalanced" tuner intended for matching
coax-fed antennas.

And, if you do match it, you'll find a relatively high RF voltage
present on the portion of the wire inside the shack. This can lead to
"RF in the shack" problems, and you may need a really good RF ground
for the tuner and rig just to keep RF voltages on the equipment
chassis from being a problem.

Here in the USA the National Electrical Code [NEC] requires that each leg of the tower be grounded at the tower approximately 1 meter from the tower. Each of the three ground rods shall be 2.5 meters long and connected together by a #6 AWG wire. The tower shall also be connected to the house 'earthing' connection at the service entrance.

The coax from the tower to the house has a directly clamped, not soldered, connection from the braid to a ground rod [also 2.5 meters long] where it enters the house. [RF travels on the inside of the braid, so this connection does not impact RF performance.] This ground rod also

connects to the 'earthing' connection.

Your requirements in GB may be different.

Lightning goes wherever lightning wants to go. After installing your tower disconnect everything from it when not in use; radios, coax cable, control cable, etc.

Also, for frequencies above 5 to 6 GHz the effects of atmospheric
absorption become much higher and non linear with frequency. It has to
do with molecular resonance and atomic cross sections of the molecules.

Reg, Yes, I have probably read and learned a good deal from stuff you have written, but I have skipped over a lot of what you have written... probably most noticeably when you and others trade kicks to the groin to see who is the last man standing.

Back on topic:

A point that you hinted at, but might have been overlooked by some is that it can be relatively unimportant that the SWR bridge's sampling line has the same characteristic impedance as the impedance at which its detector has been nulled.

For example, a typical SWR meter designed originally for 75 ohms, with a 0.1m long ideal 75 ohm sampling section, but with the detector adjusted to read nil reflected power with a 50+j0 load on the "antenna" terminals of the meter, will in most cases operate just as well as a 50 ohm SWR meter on 7MHz, as the detector will truly show when it has a 50 ohm load, the indicated VSWR for other loads will substantially correct (ie within typical accuracy for the type of instrument), and the insertion VSWR (~1.02:1) because of the 0.1m of 75 ohm line will be insignificant in practice.

In many amateur reflectometer designs (and in some commercial implementations), very little attention has been given to the characteristic impedance of the sampling section, and in some cases to the insertion VSWR (that results).

I recall testing a relatively expensive SWR meter rated from 1.8 to 150MHz, and noting that whilst it indicated a VSWR<1.1 at 144MHz on a good dummy load a Bird 43 ahead of it indicated an insertion VSWR > 1.5:1. So whilst it was good at indicating a 50+j0 ohm load on its "antenna" terminals, it was not very capable of delivering that load to its "transmitter" terminals.

Cec,
You can't measure SWR on a line which is less than 1/4-wave long.
Preferably it should be as long as 1/2-wavelength to ensure the max
and min voltage points both occur on it.

But what do you do with the SWR when you have measured it? Of what use
it?

All anybody needs to know is whether the transmitter is terminated or
is not terminated with 50-ohms. This is very important.

And when describing to a novice how your station works there's no need
to mention SWR or reflections. They are quite unecessary complications
and can be dispensed with except perhaps for trolling on newsgroups.

Reg.

I assure you I have a very good understanding of how SWR meters in
their various incantations work and how SWR works.

> The meter indicates SWR when placed at the ANTENNA end of the line. It
> is the antenna which does the terminating. And the meter gives the
> correct answers only when the line Zo = 50 ohms.

A SWR meter indicates the SWR of whatever is connected to the load
side of the meter relative to the reference impedance the meter is
designed for.

It matters not if the thing connected to the load side of the meter
is an antenna, an antenna with a transmission line, a transmission
line with a dummy load on the end, or two popsicle sticks and a
bubble gum wrapper.

If you are only interested in the SWR of the antenna and don't, or
can't, correct for the effects of real transmission line in between
the meter and the antenna, then you have to connect the antenna
to the load end of the meter directly.

> If there is a tuner or matching network in the line then the meter
> will indicate SWR on the line between the transmitter and the tuner -
> provided the meter is placed next to the tuner.

Tuners have nothing to do with the issue.

You can put a 1956 Buick on the load side of the meter; you still
read SWR of the system at the point of measurement.

It is you that is trying to confuse the issue with arm waving.

> When there is no appreciable length of line between transmitter and
> tuner (as is the very common case) there is no line on which to
> measure SWR. But the meter will indicate an SWR - and tells lies.

Babbling nonsense.

> But there's nothing to worry about just because the meter is
> indicating SWR nonsense. The meter is telling you what you really
> want to know, its exactly why you placed it there - whether or not
> the transmitter is loaded with 50 ohms.

That is not what I would want to know.

I know the output impedance of the transmitter and the line (assuming
it is good) impedance.

What I want to know is the antenna SWR and the measurement of that is
trivial though it seems to have you totally confused.

No, the measured SWR is relative to the design impedance of the SWR
meter which is normally 50 Ohms.

If you use a 100 Ohm SWR meter you get 1:1.

The SWR is a function of the TOTAL SYSTEM impedance connected to the
load side.

Replace the 100 antenna with a 100 Ohm resistor and the reading doesn't
change.

Eliminate the line and connect the 100 Ohm resistor directly to the
meter and the reading doesn't change.

The SWR of the SYSTEM, line and antenna, is NOT 1:1 for a 50 Ohm
reference.

Take the ratio of the destination antenna aperture (0.13*lambda^2 for a half wave dipole), to the surface area of a sphere, of a radius equal to the distance between the source and destination antennas (i.e. Pr/Pt). The assumption is that the source is isotropic. Massaging the above expression will produce a constant and the sum of two logs.

The SWR on the line depends on the characteristic impedance of the
line and the impedance of the termination of the line. 50 ohms does
not come into it.

The SWR on your proposed 100 ohm line with a 100 ohm termination is
1:1. If your measurement indicates anything else, then you need to
consider your measurement as invalid.

> You can't measure SWR on a line which is less than 1/4-wave long.

Because your measurements are taken 1/4WL apart, your SWR value
will be in error for all feedlines except lossless ones.

SWR can be had at any point on a transmission line.
Measure the forward power and reflected power at any point.
SWR = [SQRT(Pfor)+SQRT(Pref)]/[SQRT(Pfor)-SQRT(Pref)]

The transmission line length must only be long enough such that
the V/I ratio is forced to the Z0 value. According to some pretty
smart guys I asked, that's about 2% of a wavelength.

1186. Re: Free space pathloss calcs and factor K

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-27 02:06:58 UTC
From: Dario <dariolq@yahoo.com>
Message-ID: <1127786818.194570.169180@g43g2000cwa.googlegroups.com>
Source record: 69984

Bob Bob,
The formula for pathloss of a signal is

= 10*log10([lambda/(4*pi*D)]^2) {See any myriad of texts}

where log10 is log base 10, lambda is the wavelength, D is the LOS distance from one station to another, and of course pi is ~ 3.14. For this formula to work, lambda and D need to be in the same units. Using logarithm theorems we can rewrite it as

= 20*log10(lambda/(4*pi*D))

Using more log theorems, this equals

= 20*log10(lambda) - 20*log10(4*pi*D)
= 20*log10(lambda) - [20*log10(4) + 20*log10(pi) + 20*log10(D)]
= 20*log10(lambda) - 20*log10(4) - 20*log10(pi) - 20*log10(D)

lambda = c/f where c is the speed of light and f is the frequency (in the same unit system)

so

= 20*log10(c/f) - 20*log10(4) - 20*log10(pi) - 20*log10(D)
= 20*log10(c)- 20*log(f) - 20*log10(4) - 20*log10(pi) - 20*log10(D)

Now... we need to make sure we are using the same unit convention. If D is to be in MILES, c needs to be in miles per second.

c ~= 3*10^8 m/s
and in miles per second
c ~= 186411.4 mi/s

= [20*log10(c) - 20*log10(4) - 20*log10(pi)] - 20*log10(D) - 20*log(f)
plug into your handy-dandy calculator
= (83.4 dB) - 20*log10(D) - 20*log(f)

However, f can be refered to in GHz rather than Hertz so

= (83.4 dB) - 20*log10(D) - 20*log(F_in_GHz*10^9)
= (83.4 dB) - 20*log10(D) - [20*log(F_in_GHz) + 20*log10(10^9)]
= (83.4 dB) - 20*log10(D) - 20*log(F_in_GHz) - 20*log10(10^9)
= (83.4 dB) - 20*log10(D) - 20*log(F_in_GHz) - 180

and...

= (-96.6 dB) - 20*log10(D) - 20*log(F_in_GHz)

Note that to be mathematically consistent, when you "add" loss to a
system, you subtract a number therefore your value is actually
negative. It's mostly semantics. When you say "loss" you mean
subract.

Hope this helps!

Dario

We are not talking about SWR on the line, we are talking about SWR
at the input END of the line; big difference.

> The SWR on your proposed 100 ohm line with a 100 ohm termination is
> 1:1. If your measurement indicates anything else, then you need to
> consider your measurement as invalid.

Once again, we are not talking about SWR *ON* the line, we are talking about
SWR as seen at the input *END* of the line; big difference.

Furthermore, the SWR *ANYWHERE* on the line is *NOT* 1:1 for a 50 Ohm reference.

Try hooking a length of 93 Ohm line (which is easier to get than 100 Ohm line) terminated with a 93 Ohm resistor to any 50 Ohm SWR meter of any type.

Then hook just the 93 Ohme resistor to the meter and tell me what the difference is in the readings.

> Owen
> --

If anything is misnamed it is the term SWR.

SWR is nothing more than a dimensionless impedance ratio.

You do NOT need a transmission line to have SWR in spite of the W in SWR standing for 'wave'.

Yes, it is so and it is equal to:

SWR = (A + B)/(A - B)

Where:

A = sqrt ((R + Z)^2 + X^2)
B = sqrt ((R - Z)^2 + X^2)

R = resistive component of load impedance in Ohms.
X = reactive component of load impedance in Ohms.
Z = reference impedance (purely resistive) in Ohms

If you don't believe it, get some resistors, capacitors and a half
way decent SWR meter and do some experiments; no transmission line
required.

>> >SWR is nothing more than a dimensionless impedance ratio.

The fundamental definition of SWR flows from the behaviour and
properties of RF transmission lines.

When a transmission line is terminated in an impedance other than its
characteristic impedance, there will be both a forward wave and a
reflected wave of such magnitude to resolve the conditions that must
apply at the termination.

The forward wave and the reflected wave sum at all points along the
line having regard for their magnitudes and relative phase to produce
a "standing wave". The Standing Wave Ratio (SWR or VSWR) is defined to
mean the ratio of the maximum to the minimum of the magnitude of the
standing wave voltage pattern along the line.

The SWR on a lossless line can be calculated knowing the complex
characteristic impedance of the line and the complex load impedance.

The SWR on the line does not depend in any way on some unrelated
independent reference resistance as you suggest in your formula.

You seem to be suggesting that your redefined SWR is a really good
(obscure) way to talk about an impedance (independently of a
transmission line) in terms of some standardised reference value, and
you can throw away the fundamental meaning of SWR to support your
SWR(50) concept. In your terms (independently of a transmission line),
for instance, a Z of 60+j10 would be SWR(50)=1.299, and so would an
infinite number of other Zs have SWR(50)=1.299... how is that of
value. To know Z is 60+j10 is to know more than to know SWR(50)=1.299.

Owen

Owen,

SWR meters with a sampling line.

The only experience I've had has been I once made one for HF. It was of the type where a second wire is drawn alongside the inner conductor of a short length of coaxial line of impedance in the same street as the system it is to work with.

Operating frequencies covered the whole of the HF band. That is a very wide band. Which indicates that line length plays no part in measuring accuracy once calibrated.

To explain how the thing works it is necessary to return to what it really is. It is a resistance bridge. All so-called SWR meters, whatever the circuit or form of construction, are resistance bridges.

The bridge has 3 internal ratio arms. The 4th arm is the variable transmitter load. If all 4 arms are of same resistance we have a very sensitive arrangement suitable for QRP transmitters. However, 3/4 of the TX power is dissipated in the 3 internal bridge arms.

For higher power transmitters it is necessary to use high ratios for the ratio arms. In the case of meters which use a little ferrite ring as a current transformer, a resistor of the order of 30 to 100 ohms can be shunted across the current transformer secondary winding while the primary winding has an input resistance of the order of 0.1 ohms which forms the value of the ratio arm in series with the external load. This 0.1-ohm arm is capable of carrying the load current of several amps with only a small power loss.

The other two ratio arms can be a pair of high value resistors in the same ratio as occurs via the current transformer. If the input resistance of the current transformer is 0.1 ohms then the bridge ratio is 50 / 0.1 = 500:1 where 50 ohms is the usual value of the load resistance when the bridge is balanced and SWR = 1:1

The two high impedance arms can be capacitors in the same ratio of 500:1 which have zero power dissipation but have a minor effect on accuracy. They introduce a small phase angle into the load as seen by the transmitter through the meter. The error increases with increasing frequency.

It will be seen that the take-off point is effectively the same for both current and voltage.

Returning to the so-called sampling line.

There is a bridge configuration which is not quite so obvious. But instead of a current transformer the current is picked off by means of a short length of wire in parallel with the coaxial inner conductor by virtue of their mutual inductance. The line is too short for propagation effects to play a significant part.

Voltage is picked off at the same point by virtue of the capacitance between the wire and coaxial inner conductor. The phase relationship between volts and amps can be reversed just by reversing the direction of propagation through the meter.

The bridge ratio is set partially by the ratio of the impedances Zo of the additional wire and inner coax conductor. The length of coaxial line affects only the bridge sensitivity and power dissipated in the meter. As you must be aware, sensitivity falls of fast with decreasing frequency and 160 meters was my favourite band. So the home-brewed meter was soon discarded and I returned to ferrite rings.

I was left with the impression it was very easy to make and that almost anything would work.

Hope you can understand the foregoing.

Reg.

I was taught as a child to help others. I have lost count of the things I've done for family, friends and strangers without asking anything in return. I have also had others help me when the tables were turned. They have fed me, given me rides, or paid so I could see a doctor after I was fired for being unconscious for five days with the flu. It works both ways. Today, I am 100% disabled, and only able to work a couple hours a day so I spend most of that time collecting and repairing donated computers for the local "Vets Helping Vets" group, who gives them to other disabled vets who are unable to afford a computer. It gives me something to do, and still helps others. I have offered to help the hams around here to repair their equipment, but they dismissed my offer because I don't have a amateur radio licensee. Its their loss. I have a well equipped shop here at home, and a good stock of parts going to waste. I guess working on a 195 UHF KW transmitter or building commercial microwave equipment isn't good enough for them? It doesn't matter to me anymore. I'll keep restoring early amateur and general coverage receivers as long as I'm able to prop myself up at one of my benches. My current project is a National NC-183R that is taking way too long to restore because it was butchered by an EE with too much time on his hands. There are huge wads of capacitors taped together with wires running everywhere under the chassis so I will make sure I have every part before I clean up that mess.

Jim,

Perhaps there's some misunderstanding about location of the meter and what it is measuring. Let's try to clear it up.

Would you please do us both a favour by answering the following simple question?

There is a 50 ohm line feeding a 100 ohm antenna.

There is an SWR meter located at the line-antenna junction.

The meter has a reading. Does the reading apply to SWR of the antenna, or does it apply to the SWR along the feedline?

Antenna or Feedline?

Reg.

Hello, and I don't think that a comparison between snake-oil antennas (e.g. E-H and crossed-field types) and fractal antennas is justified. What has compelled you to reach this conclusion? Marketing-hype aside, numerous papers with measured data on fractal design have been published in the IEEE's Transactions on Antennas and Propagation. The Electroscience Lab at Ohio State Univ. has been investigating fractal designs for a while now. An sntenna based on a fractal pattern is one method (not the only one) of placing an antenna in a small space but not having it too short electrically. I think it's too early to say whether or not fractal antennas will be the preferred technique for packaging commercial/military antennas into small footprints such as handheld radios. From what I've read the technology shows promise. Sincerely, and 73s from N4GGO,

Can someone please tell me how to 'paste' a copy of text into the 'text' portionof a new message?

Walt

To copy & paste text or basicly anything into a new page. With your mouse, place the curser on the left hand side of the start of your choosen text. Next, keep your finger on the left mouse button, dragging the curser across your choosen text until it is all highlighted. Now clik with your right mouse button and a drop down box will appear, clik copy. The copied text is now on the clipboard. In your new document, right clik again and the drop down box appears once more. Clik paste, and the copied text will now appear in your new document page. The other explanations in this thread are via the key board. Simple really, have fun. Dave. The drop down box is self explanitary.

It applies to the match of the RF network that follows the SWR meter to the impedance for which the SWR meter was calibrated.

And if in your example the SWR meter has been calibrated for 50 ohms, and is moved to the input end of that line+antenna RF network, it will also have a reading -- which will be the same as when it was inserted at the antenna-line junction, less the round-trip RF attenuation of the transmission line (assuming that the transmission line is 50 +/- j0 ohms throughout its length).

In fact it is a common practice to optimise the transmission line/antenna match of commercial FM and TV broadcast antenna systems by use of a variable transformer inserted at the antenna input, whose adjustment is made by reference to the far-end reflection seen at the sending end of the transmission line, using a high-directivity reflectometer, or SWR meter.

The same physics applies to ham antenna systems and methods/means of measurement.

The pickup lines in my Heathkit HM-15 are terminated on one
end with a 50 ohm resistor. One pickup line thus attenuates
the reflected traveling wave and allows the forward traveling
wave to be rectified. The other pickup line attenuates the
forward traveling wave and allows the reflected traveling wave
to be rectified. Knowing the peak values of both of these two
traveling waves allows a calibrated meter to indicate SWR.

fractal antennas in this newsgroup got a bad rap from some rather abrasive
discussions in the past. at least when properly analyzed fractals perform
as predicted. the problem in here was that they were compared anecdotally
to full size antennas without proper analysis. and the regular poster had
professional commercial interests in fractal antenna products which led to
arguments about commercial use of the group, patent infringement, and all
sorts of lawsuit threats.

And power=EI. And it also equals I^2*R and E^2/R.

SWR can be expressed in terms of power ratios, current ratios, and
impedance ratios.

> When a transmission line is terminated in an impedance other than its

Is is also defined as a current ratio and an impedance ration.

> The SWR on a lossless line can be calculated knowing the complex
> characteristic impedance of the line and the complex load impedance.

What no waves, just impedences!! Now you are contidicting yourself.

> The SWR on the line does not depend in any way on some unrelated
> independent reference resistance as you suggest in your formula.

Read it again.

The R is the R of the thing at the end of the line.

The X is the X of the thing at the end of the line.

The X is the impedance of the line.

> You seem to be suggesting that your redefined SWR is a really good
> (obscure) way to talk about an impedance (independently of a

> value. To know Z is 60+j10 is to know more than to know SWR(50)=1.299.

The equations given are general and can be derived from first priciples.

The Z in the equations is the Z of your reference, i.e. 50 for a 50
Ohm system.

SWR is *ALWAYS* relative to some reference impedance.

> There is an SWR meter located at the line-antenna junction.

What does this mean?

> The meter has a reading. Does the reading apply to SWR of the
> antenna, or does it apply to the SWR along the feedline?

The reading is the SWR at that point.

> Antenna or Feedline?
> ----
> Reg.

An SWR meter reads the SWR of the thing connected to its output port
with respect to the reference impedance the meter was designed for.

The SWR meter reads the SWR *AT THE POINT OF CONNECTION* of the
connected system.

Not the middle of the system, not the other end (if it has one)
of the system, but the input point.

If you measure a SWR (50 Ohms reference) of 2:1 for a black box,
what is in the box?

A. A 25 Ohm resistor.
B. A 100 Ohm resistor.
C. A cable spool of coax with some impedance at the end of it.
D. Could be any of the above.

In general there is no guarantee that the SWR at any point of a
transmission line will be equal to the SWR at any other point on a
transmission line other than for special cases.

What seems to have you terribly confused is that all the transmission
lines, tuners, antennas, connectors and whatevers become a *SYSTEM*
and the SWR at the input connector to the *SYSTEM* is not guaranteed
to be the same as the SWR at some arbitrary point inside the system.

When you measure the SWR of a line with a load on the end, you are measuring the SWR of the entire system relative to your reference, not the load.

Cec, you have YOUR explanation and I have MY explanation.

Which is the most simple?

There is a bridge.

When the variable arm, the load, is 50 ohms the bridge is balanced and the meter indicates SWR = 1:1

When the variable arm is either 0 ohms or infinite ohms, the meter indicates SWR = infinity :1

What can be more simple than that? How it works can be visualised.

But the meter is ambiguous. It cannot distinguish between loads of 0 ohms and infinite ohms. Additional information is required.

This serious ambiguity also applies to your weird contraption. ;o)

Richard,

If's and But's are not required.

The antenna is just an arbitrary load.

Does the meter reading indicate SWR on the feedline (which is what is usually required), or does it not?

This is not a "catch question". It is not a troll.

"Antenna or Feedline?" please.

KISS

Reg.

Reg Edwards wrote:
> Cec, you have YOUR explanation and I have MY explanation.

Mine is a lot simpler. The Heath HM-15 has two pickup elements.
If you install a Z0 resistor load at one end it "picks up" the forward
wave. If you install a Z0 resistor load at the other end it "picks up"
the reflected wave. The two pickup voltages are rectified and compared
through a calibration procedure.

The parts that came with the HM-15 kit in the 50s-60s included two
72 ohm resistors. RG-ll was very popular at the time. If one wanted
a 72 ohm SWR meter, one installed the 72 ohm resistors. If one wanted
a 50 ohm SWR meter, one installed the 50 ohm resistors. A switch could
be installed that switched between 50 ohms and 72 ohms calibration.

> This serious ambiguity also applies to your weird contraption. ;o)

Actually, the Heathkit design concept is easier to understand than
is the bridge explanation or the toroid-pickup/phasor-addition
explanation. The first SWR meter I built in the 50s, used two
lengths of insulated wire shoved under the braid of the coax.
It worked but, at the time, I had no idea why it worked. Heath's
little slotted line pickup device was pretty slick. I sometimes
see them for sale at hamfests.

Hi John,

Don't you see a bit of disconnect between these statements?

How long do you think it took Marconi to go from experimental antennas to science, to production? And this was from when they banged rocks together, not after a century of introspection on the subject.

To answer my question, and to show the perspective of failure for fractals:
At the age of 19 he was performing his first experiments with antenna and transmission of RF;
At the age of 22 he had his first patent for same;
At the age of 27 he transmitted across the Atlantic;
At the age of 35 he was awarded the Nobel Prize for all things considered.

Well, we won't go as far as the Nobel; after all, it requires some demonstration of a unique contribution to science. But on the other hand, "research" on fractal things are all expressed in the same breathless excitement of "discovery" and yet they've been circling the same arid landscape like vultures in search for carrion.

Let's simply look at the science stripped from these gushing claims, and the teary-eyed exultation that attends fractals. The simple dipole or monopole have a not to complex formula for the description of their drive point Z. Name one formula (that is not my own) that does so for fractal antennas. There is a very simple formula for correlating the resonance of a wire antenna frequency/length. Name one formula (that is not my own) that does so for fractal antennas.

I've read a lot of this tripe that endlessly re-discovers the Koch Triadic/Quadratic/.... Unless you've come across some remarkable treatise that reveals correlations that uniquely associates the fractal math with the technical outcome, then such fluff pieces are academic masturbation.

The golden glow on the horizon:
>the technology shows promise.
as sincere as it is, has no justifiable basis beyond the same emotion

stirred with the promise of snake-oil curing ____. This field has been tilled for a decade (cohen keeps inflating his resume to push that further back) and no new age has grown from that effort. As such, Marconi captured the world's imagination in less time, and we have the math to correlate the reality of that achievement. Clearly the sum of the 21st century researchers of fractal antennas do not equal the total of one 19th century Italian gentleman dabbler.

Hi Reggie,

Without recourse to that "additional information," explain how you
achieve the unambiguous by your method of probing lines (be they
parallel, coaxial, or waveguide).

In other words, your objection is a non sequitur, it is meaningless
because you need the same additional information and you cannot
demonstrate any measurable difference between the manifold methods of
coming to the same determination.

Of course, if you throw a spanner in the other guy's gear-box, you
might win the race.

No, of course it isn't (must be all those other posts then)
>"Antenna or Feedline?" please.
>KISS

Hi Reggie,

Ah yes! That "additional information" finally surfaces as a
requirement doesn't it?

SWR "on the feedline" is like dust thrown into the eyes of the rubes
before the elephant appears in front of them. Presumably, "on the
feedline" is akin to the ark holding a sacred artifact like the finger
of St. Heavybottom.

The traditional slotted line used for probe determination of SWR comes
with two connectors like that commonplace SWR meter (and the slotted
line probe connects to a - SWR METER! albeit, not the commonplace
variety, but odd how the tide of time has not yet altered the name to
TLI). And if we were to substitute the slotted line for commonplace
SWR (or t'other way 'round), both/either/each would face the same
issues and offer the same results. Imagine that, not a whit of
difference, except that the probes can add error through in-expert
use. Whoops! Same issues of how things can/do go wrong.

So, the ultimate question of the universe (yadda-yadda-yadda) is what
difference does having a transmission line between these two
connectors make on the outcome of what SWR exists AT the load
connector? A rhetorical difference! After-all, you would need
"extraordinarily more information" to express where the SWR resided,
wouldn't you? ;-)

Any artificial constraint you toss in as an objection exists for
yourself as well. I can see Kelvinator swinging his cane now. Did I
say lower 6th? They would probably hoot you down to upper 5th.

Rich, thanks for the smooch.

But I'm afraid you are wrong. The meter correctly indicates SWR on the feedline when it is located at the antenna end of the line.

But don't worry too much about it. It seems you are in good company. So much for the technical education of radio engineers.

It all comes about because of so-called SWR meters being called SWR meters - which they are not. At least not when located at the transmitter end of transmission lines as they nearly always are.

When located adjacent to the transmitter they are TLI's. Transmitter Loading Indicators. And SWR has very little or nothing to do with it.

Reg Edawds, G4FGQ wrote:
"R&B`s cavity magnetron was developed at Birmingham University in the midst of the air raids on that industrial city."

Prior to Randall & Boot, magnetrons were low-power devices, outclassed ny klystrons. R & B`s resonant-cavity magnetron, operating at 10 cm exuded 100x more power than previous magnetrons and allowed smaller hardware and imptoved image definition.. The 6 KW GEC manufactured version given to the U.S. in August 1940 was shipped by ordinary parcel post to arouse no suspicion of its importance. It has been called the most important shipment ever to arrive on U.S. shores.

The resonant-cavity magnetron was an awesome contribution to victory in WW-2 against both Germany and Japan. Their radar development lagged far behind.

My ship in WW-2 had only one spare part kept in the captain`s safe, the Raytheon resonant-cavity magnetron for our Raytheon navigational radar system. Fortunately, we never needed to replace it.

After WW-2, Rayrheon shifted production to their bew "Radar Range". The Japanese soon caught up with their ubiquitous microwave ovens. They were more motivated. Our houses were already equipped with oil, gas, and electric ranges aplenty. Everyone, it turned out, was ready for microwave too.

Klystrons were not washed up either. The most powerful generators ever built were klystrons. The speed detector used to ticket your car probably uses a laser. All radar isn`t pulsed radar. Radar altometers use separate transmitter and receiver antennas. They transmit an FM signal whose modulation frequency is changing at a certain rate. This is continuously compared with the modulation frequency of the received echo to tell how far away the reflection point is.

The television signal you watch off the air was probably generated by a large klystron.

Best regards, Richard Harrison, KB5WZI

"Reg Edwards"
> But I'm afraid you are wrong. The meter correctly indicates
> SWR on the feedline when it is located at the antenna end
>of the line.

Remove the feedline, and connect the 100 ohm antenna through the SWR meter calibrated for 50 ohms, directly to the transmitter. The meter has a reading. The measurement will have the same value as before, neglecting any adjustment for having no line loss now. But there is no feedline, so how can there be any SWR on it, you write.

The fact that there is not enough transmission line length in the system for literal standing wave maxima and minima to develop on it does not mean that reflections do not exist in the output load system. It is the value of those reflections that determines the corresponding value of SWR. Reflections can be measured by appropriate instruments regardless of the length of line in the measured system, or even the existence of any transmission line at all.

The convention of the professional engineering community for many decades has been to convert incident and reflected waveform samples into the corresponding value of SWR, no matter if there is insufficient line length in the system for the corresponding maxima and minima to develop fully on it. It doesn't matter, electrically. Your constant diatribes stating that it does is a futile exercise.

Disable the SWR protection in your ham tx and key it to full power into an open or short. There is no transmission line where standing wave maxima and minima could exist, but your tx will burn up anyway.

Maybe save your response until tomorrow morning, when your Merlot buzz has worn off :)

Teg, G4FGQ wrote:
"Err, no, the meter is telling what it sees at the point of measurement."

Yes, and that is a ratio depending on "rho", the reflection coefficient.

We know that rho equals:

the square root of reflected pwr / fwd pwr

And: VSWR = 1+rho / 1-rho

VSWR is a function of the reflection coefficient

You drive an automobile and glance at the speedometer. It is an electrical meter giving an indication proportional to vehicle speed.

You look at an SWR (TLI) meter giving an indication calibrated to be proportional to SWR.

Best regards, Richard Harrison, KB5WZI

> _____________

PS:

In this example the mismatch between the antenna and the line is the source of the reflection that results in system SWR. Convention is to state that the SWR belongs to the antenna, not the line -- although the added stress on components applies only to the line and tx, and not to the antenna.

An ideal SWR meter will read that antenna reflection to have the same value when installed at either end of the line, or anywhere along its length (assuming
a perfect 50 ohm line, and neglecting line loss).

Jim, your comments are full of inconsistencies (like pronumeral X
having two different meanings in the same formula, equations described
as "general" but which do not allow for a reactance component in your
"reference z" which is actually the characteristic impedance of the
line in the real world, equations derived from first principles and
you state the first principles are "irelevant").

In the absence of logic in your writing, I won't waste anymore time...
you have some deeply entrenched misconceptions and seem to have built
a large framework of simple views (like power=EI... a DC circuits
concept) to support the misconceptions.

1242. UWB pulse signal has no DC? Why?

Newsgroup: rec.radio.amateur.antenna
Date: 2005-09-27 21:44:43 UTC
From: Harry <harry0d88@aol.com>
Message-ID: <1127857483.866370.308610@z14g2000cwz.googlegroups.com>
Source record: 69889

It is said that a transmitted UWB pulse should not have any DC because of the transmitting antenna:

"Without getting into the details of the physical generation of UWB waveforms, it is sufficient to note in this regard that the transmitting antenna has the general effect of differentiating the time waveform presented to it. As a consequence the transmitted pulse does not have a DC (direct current) value-the integral of the waveform over its duration must equal zero."

(page 4,
http://www.antd.nist.gov/wctg/manet/NIST_UWB_Report_April03.pdf)

Would someone please explain that for me?

Thanks!

> Just answer the obvious question. No If's or But's

I did answer the question, Reg. You just didn't like the
answer.

Let's say we have an SWR meter at point 'x' in the following
diagram:

XMTR---1WL 50 ohm coax---x---1WL 75 ohm coax---100 ohm load

If the meter is calibrated for 50 ohms, it will indicate the
SWR on the 50 ohm coax, 2:1, on the source side of the meter.

If the meter is calibrated for 75 ohms, it will indicate the
SWR on the 75 ohm coax, 1.33:1, on the load side of the meter.

An SWR meter samples the magnitude and phase of the voltage,
samples the magnitude and phase of the current, assumes
it exists in the Z0 environment for which it was calibrated,
and accurately reports those results.

If the SWR meter is installed in a Z0 environment other than
that for which it was calibrated, the instrument is being
misused and the operator is at fault, not the instrument.
Any instrument can be misused.

The last line is obviously a typo, it should be:

The Z is the impedance of the line.

Z is an impedance. An impedance is an absolute value.

The impedance of RG-8 coax, for example, is approximately 50 Ohms.

As I said, if you don't believe the equations, go get some resistors
and capacitors and do an experiment.

Until you do that you have no case.

Sigh, the power thing was a simple illustration of the fact that a
thing can often be represented a number of different ways.

How about acceleration is the first derivative of velocity and also
the second derivative of position? Do you like this example better?

And if you think it is calibrated in km/hour when it is
actually calibrated in miles/hour, your speed reading will
be in error and you may get a ticket. This is akin to an
SWR meter being calibrated for the wrong Z0.

Hi,

As anyone a paper or electronic manual for the HP 1707B Hewlett Packard
Oscilloscope. I believe there is an A version, which I think would be
o.k.

Maybe know of a website where it can be downloaded, preferably for free

Will pay for any postage or materials if required.

Here's an interesting study on the subject, it says:

http://www.timesonline.co.uk/article/0,,2-1798944,00.html

"RELIGIOUS belief can cause damage to a society, contributing towards high murder rates, abortion,
sexual promiscuity and suicide, according to research published today.

According to the study, belief in and worship of God are not only unnecessary for a healthy society
but may actually contribute to social problems.

The study counters the view of believers that religion is necessary to provide the moral and ethical
foundations of a healthy society."

Lightning generally goes wherever it decides. However, I have been advised that it generally dislikes sharp turns in conductors it happens to follow. Think of this as a "quarter turn" and as a result represents some inductance and therefore a little more impedance that the straight path. With these super high currents, that's a lot of magnetic field around the conductor. A look at the mag field and that is must be compressed inside the quarter turn, should help you to see this concept. With this in mind, the turn at the bottom of the tower can be where a coax (shield)ground can go, thus encouraging conduction to ground. Having the required tower ground at this point also 'encourages" the blast of current to take that path rather than the coax.

Remember, however, that

1- There will still be significant voltage on the coax, even if the strike goes down to the closer tower ground. This will be up to and can exceed any suppressor placed there.

2- This current can and does produce very large induced currents in ALL near-by conductors, so any and all nearby wires will sustain high voltages. (many a time I have heard a small click in the house which happens along with a near-by strike (not delayed) Flash simultaneous with click, then boom fraction of a second later.

3- Put an analog VOM on your antenna some time - either when rain is near or not. It can be on the ma ranges or volts, doesn't matter because of the way they are made. For a DVM only the ma range, but it's not as dramatic as the needle moving. Watch it gradually build up to some current (micro amps to ma) Then it will collapse or go negative when lightning strikes near by. Try connecting the meter across the antenna feed line or from either/both feedline sides to ground. Tx disconnected.

>Would someone please explain that for me?

Hi Harry,

Because the media, space, does not have DC continuity, but acts rather more like an infinite succession of inductances and capacitances that transforms the original waveform (a) into (b) whose DC average is zip. It should be said that this is not due strictly to the antenna, but all paths within the complete communication circuit.

And to anticipate the yahoos who interject that yes there is an R component, its contribution (short of the ï¿½ther turning into a plasma) is of no consequence to the outcome you observe.

This is an answer, but it may fall quite short of an explanation.

With a ns pulse into a zero resistance conductor in free space all
energy should be radiated, so no DC component if you look at the input
power. However if you introduce the same pulse to a circuit that has
magnetic properties, i.e. a ferrite inductor as an example, there is
energy used to align the molecules in the material, not radiated, which
results in a DC component. In a flashlight, most of the energy is
heat, which will result in a big DC component with no radiation rf
wise.
That's really advanced stuff for a Ham Radio Newsgroup.

In this particular case, quantum mechanics offers the
easiest-to-understand explanation. As Feynman put it:
"So now, I present to you the three basic actions, from
which all the phenomena of light (including RF) and
electrons arise.
-Action #1: A photon goes from place to place.
-Action #2: An electron goes from place to place.
-Action #3: An electron emits or absorbs a photon."

many a time I have heard a small click in the house which happens along
with a near-by strike (not delayed) Flash simultaneous with click,
then
boom fraction of a second later.

I' ve heard that arc many times at my ground connection
just outside the window. Sometimes with strikes that might
be a few blocks away. As far as the "click" one usually hears
with a super close strike, according to Gary Coffman, he claims
that is picked up directly by the auditory nerve, if I remember right.
Even deaf people can hear that "click". When my mast got struck,
which is like 10-15 ft away from me, the sound was like a lightbulb
being thrown on the ground outside my window. Of course, the
sonic boom is much louder...:/

Harry,

Forget all the nonsense about photons, continuity of space, and other blather. This is simply a matter of mathematics.

In general the initial waveform will consist of a constant DC level and a number of AC components. Any DC component in the original pulse is lost when the pulse is differentiated by the transmitting antenna, leaving only the differentiated AC components. Therefore the integral of the differentiated waveform has a zero DC value. Of course one could always add in a constant to the integrated result, but that would not have much physical meaning in the context under discussion.

73,
Gene
W4SZ

There is no mystery about the 'required additional information'.

The nearest the so-called SWR meter ever gets to measuring anything is the "magnitude of the reflection coefficient", MRC, which arises due to the impedance of whatever is presented to the meter's output terminals. (Recall, this impedance is the 4th variable arm of the meter's RF resistance bridge.)

This impedance can have an angle anywhere between 90 and -90 degrees. And the MRC can have an angle in any of the 4 quadrants, ie., anywhere between 0 and 360 degrees.

But the meter is capable of indicating ONLY the MRC. All the angle information is lost and gone forever. This is equivalent to losing information about the location along the line of the peaks and troughs in the standing wave. That is, of course, if a long line extending back from the input of the meter to the transmitter actually exists.

Now, if the line with standing wave exists, the magnitude of the SWR can be calculated from -

SWR = (1 + MRC) / (1 - MRC)

or the meter scale can be calibrated in terms of SWR.

It is frequently thought the SWR can be used to calculate the power lost in the line. But, particularly when the the line is less than 1/4-wavelength long, this is not so. It requires the location of peaks and troughs to be known - which they are not.

It is also thought that by rearranging the equation it is possible to calculate the reflection coefficient from the indicated SWR. Wrong again - can't be done, and in any case the reflection coefficient is useless without an angle.

So the indicated SWR is not of much use except to provide a topic of conversation. On the other hand, just by recalibrating the meter scale, you can have a valuable, indispensible TLI.

By the way, I hear Californian wine makers have been hijacking the names of French grape-growing districts and have been obliged to re-calibrate their bottles. Ah well, back to the Chilian stuff.

Hi Reg,

Of course, no one thought so except you - until now, and you still
have nothing to offer that distinguishes the probe method from the
common SWR meter available to every CB operator.

>By the way, I hear Californian wine makers have been hijacking the
>names of French grape-growing districts

Boy, are you late in taking in your newspaper. This has been going on
since the American vineyards saved the French lines from a devastating
rust blight decades ago. There is no original French line that has
not been re-planted from American root cuttings for half a century or
more after the Germans tilled their soil with Stukas.

The conclusions he draws are a convolution of logic.

1. The US is a religious country.
2. The US has a high murder rate
3. The US has a high rate of VD, drug use, and aids.

He concludes that statements 2 and 3 are caused by statement 1.

Utter nonsense, at the risk of upsetting liberals I would suggest that 2 and
3 can can more easily be tied to minorities than religion.

What does it mean by "when the pulse is *differentiated* by the
transmitting antenna" ?

Can I say that because an antenna can be modeled as a series of
inductors and capacitors like a transmission line, the DC part of the
pulse won't radiate from the antenna?

Another bit of good advice. Run your coax down the tower on the INSIDE
of the tower [in the space created by the three legs].

I don't see the point here. Marconi was dealing with rather elementary (and physically large) wire structures and did not have to generally concern himself with design issues such as antenna gain/radiation pattern, efficiency, driving point impedance, size, weight, etc. Back in Marconi's time it might have gone down like this: Try it and see if it works. Wow, it works! Now if we could time-travel to that era we could ask: Could we tweak the antenna for higher gain? Is the transmit antenna optimally matched to our spark-gap transmitter? Gosh I don't know. What's antenna gain?

Packing an antenna with required performance, for example, into a cell phone is not as simple as it sounds. I don't see any reason to get in a dither over a particular antenna type if its performance is well documented and its theoretical basis is in concert with (does not violate) electromagnetic theory. Granted, I do see a heck of a lot more papers on patch antennas than I do fractal types but so what? I don't ever remember seeing any papers on E/H or crossed-field antennas in any IEEE pub nor do I ever expect to. I'm also very leery of antenna performance claims and specious explanations provided by websites such as www.antennex.com even though a lot of their contributors are our Canadian ham brothers. An amateur radio license does not make one an antenna engineer. The ham may be a prolific inventor/tinkerer, perhaps with some applicable technical knowledge that facilitates him/her "stumbling" upon a great antenna design. But he/she is not an antenna/electronics/electrical engineer

(unless they have pursued that course of study). Sincerely,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

Son, I SAY, Son! I ain't no chicken! Now that over there, THAT's a
chicken!.........

Actually, Ol' Foghorn is probably not the problem. There are a number
of old WB cartoons that have some rather strong stereotype of the folks
we were fighting during WWII (the big one) Considering that they are now
our allies, there might be a little sensitivity thing going on.

Personally, I think they should be shown, especially when introduced in the proper context. They are of historical value, and in the context of the times, were understandable.

Oh - and they were darn funny too!

I wouldn't doubt it. The stronger the religion, the worse the evils
have to be. They are partners. One must have the other.

There was a series a few years ago, called "The Pagan Invasion". It was
broadcast on one of the national Religion channels. I used to watch it
because there was some pretty decent 3-D animation in it. (for the time)
But when you saw what those folk believed in, it was downright scary.

If those folk were to come into power, there is no doubt that the Salem
Witchcraft trials would be a role model for government.

Hopefully, the lengths to avoid are associated with specific
loads. Avoiding 1/4WL of ladder-line when feeding a 1/2WL
dipole may be good advice but 1/4WL of ladder-line is ideal
for feeding a one wavelength dipole.

In my no-tuner system of tuning, the peaks and troughs are known.
The purely resistive current maximum point is always located at
the balun/choke.

A lot of those American wine-making families had French roots. :-)

Dave wrote:
"And what is that really supposed to do?"

"That" may be the suggestion to run the coax inside the tower or strapped to a leg.

Lightning is a transient electric current which follows the path of least impedancee. A conductive tower has more cross section and therefore less inductance per unit length than a coax cable. When the cable is in close proximity with the conductive tower, it is likely the lightning will prefer the tower to the cable for a path to earth. If the tower is wood or plastic, run the coax inside steel conduit.

The tower should better support the lightning than the coax.

Another good suggestion was to ground each leg of the tower, 3 or 4 usually, to its own substantial ground rod. This lowers impedance of the earth connection. The heavy cables connecting the rods should be run outside the concrete block used as a tower base to bypass lightning current around the concrete which never completely dries. Its contained moisture can form steam from an enormous electric current blasting the block asunder.

Best regards, Richard Harrison, KB5WZI

Absolutely. I don't support money going to rebuilding NO in it's present spot.

The French Quarter is okay where it is. It will eventually become an island, and should last for quite a while yet. Seems like a charming way to get to Mardi Gras - by a boat.

But no matter how much money we pour into th erest of NO, it will sink. I suppose that we could try a Netherlands type approach, with huge dikes and all, but I doubt that there is enough room on the sides to do that, and besides, the Netherlands doesn't have to worry about hurricanes either.

Reading This Will Change Your Life!!!

Imagine waking up every day knowing that you don't have any financial worries. Imagine going to bed every night feeling completely at PEACE because you and your loved ones are financially secure.

A little while back, I was browsing through a newsgroup, just like you are now, and came across an article that said you could make thousands of dollars within weeks with only an initial investment of $5.00! So I thought, "Yeah right, this must be another scam", but like most normal humans, I was curious, so I kept reading... I also did an Internet search (I did not want to be caught by another get rich quick scam), and found nothing but success stories.

It said that you should send $1.00 to each of the 5 names and addresses stated in the article. You then place your own name and address in the bottom of the list at the 5th position, and post the article in at least 200 newsgroups. (There are thousands)

No catch, that was it.

So after thinking it over, and talking to a few people first, I thought about
trying it. I figured "what have I got to lose except 5 stamps and $5.00, right?" People spend $5.00 on things that bring MUCH less return than this does!

Then I invested the measly $5.00 (Yes I used the word "measly" because $5.00
really is a measly amount compared to the money I have made through my initial
investment).

Well GUESS WHAT!!

... within 7-10 days, I started getting money in the mail! I was shocked! I figured it would end soon, but the money just kept coming in. This is so amazing, in my first week, I made about $25.00. By the end of the second week I was thrilled to discover that I had made a total of over $1,000.00! Oh my God, in the third week I had over $10,000.00 and it's still growing.

I Realized...This Is How Life Should Be!!
And I Guarantee You Can Live This Way Right Now!!

This is now my fourth outstanding week and I have made just over $42,000.00 and
it's still coming in rapidly. It's certainly worth the $5.00, and 5 stamps, I have spent more than that on lottery tickets!! Make sure you print a copy of this article NOW, so you can get this fantastic information when you need it.

Let me tell you how this works and most importantly, why it works...

I promise you that if you follow the directions exactly, that you will start making more money than you thought possible by doing something so easy! Read this entire message carefully! (print it out or download it). Follow the simple directions and watch your money pour in! It's easy, It's legal, and...

It's The Perfect Opportunity At The Perfect Time!!
I'm Dead Serious!!

VERY IMPORTANT: This is not a rip-off; it is not indecent; it is not illegal; and it is virtually no risk - This is the best deal ever, and it really works!!! If all of the following instructions are adhered to, you will receive extraordinary dividends from an investment is only $5.00 (Plus postage).

PLEASE NOTE: Follow these directions EXACTLY, and $50,000 or more can be yours in 20 to 60 days. Don't you think it's time for your dreams to come true? It has nothing to do with luck, this is a very powerful, and truly amazing system that has proven to increase the fortunes of ordinary people time and time again.

The Bottom Line Is This

This program remains successful because of the honesty and integrity of the participants. Please continue its success by carefully adhering to the instructions.
You will now become part of the Mail Order business. In this business your product is not solid and tangible, it's a service. You are in the business of developing Mailing Lists. Many large corporations are happy to pay big bucks for quality lists.

Here are the four easy steps to success:

STEP 1:

Get 5 separate pieces of paper and write the following on each piece of

paper "PLEASE PUT ME ON YOUR MAILING LIST." Now get 5 US $1.00 bills and place ONE inside EACH of the 5 pieces of paper so the bill will not be seen through the envelope (to prevent thievery).

Next, place one paper in each of the 5 envelopes and seal them. You should now have 5 sealed envelopes, inside each envelope should have a

piece of paper stating the phrase...

"PLEASE PUT ME ON YOUR MAILING LIST."
(please add your printed name and mailing address under this phrase)

Remember: A US $1.00 bill, as payment for your name going on the mailing list, must also be in each envelope.

What you are doing is creating a service. THIS IS ABSOLUTELY LEGAL! You are requesting a legitimate service and you are paying for it! Like most of us I was a little skeptical and a little worried about the legal aspects of it all. So I checked it out with the U.S. Post Office (1-800-725-2161) and they confirmed that it is indeed legal!

Mail the 5 envelopes to the following addresses:

1) J Roth
2901 Barton Skyway 3406
Austin, TX 78746
2) Jesse James
1778 Swift Ave.
Ventura, Ca 93003
3) Andrew L
P.O. Box 84
Cardinal, VA 23025
4) Jake S
4561 w mcnab rd #17
Pompano beach, Fl 33069
5) Jack P (A1)
13 Roosevelt Place
Brooklyn, NY 11233

STEP 2:

Now take the 1st name off the list that you see above, move the other names up (5 becomes 4, 4 becomes 3, etc...) and add YOUR name as number five on the list.

STEP 3:

Change anything you need to, but try to keep this article as close to original as possible. Now, post your amended article to at least 200 newsgroups. (I think there are close to 32,000+) All you need are 200, but remember, the more you post, the more money you make! This is perfectly legal! If you have any doubts, refer to Title 18 Sec. 1302 & 1341 of the Postal lottery laws. Keep a copy of these steps for yourself and, whenever you need money, you can use it again, and again.

PLEASE REMEMBER that this fantastic program remains highly successful because of the honesty and integrity of the participants and by carefully adhering to all the directions. Look at it this way. If you are of integrity, the program will continue, and the money that so many others have received will come your way.

NOTE: You may want to retain every name and address sent to you, either on a
computer or hard copy and keep the notes people send you. This VERIFIES

that you are truly providing a service. (Also, it might be a good idea to wrap the $1 bill in dark paper to reduce the risk of mail theft). So, as each post is downloaded and the directions carefully followed, five members will be reimbursed for their participation as a List Developer with one dollar each. Your name will move up the list geometrically so that when your name reaches the ..1 position you will be receiving thousands of dollars in CASH!!! What an opportunity for only $5.00 ($1.00 for each of the first five people listed above). This AAA system is very legit, and is perfect for creating financial security. This program is also worth 100x the amount you will spend to start it.

Special Bonus Offer

Thanks to PayPal and the Internet, this investment is now virtually ZERO! And what's more, the entire process is FASTER, EASIER, and MORE LUCRATIVE than it has EVER been!

I WAS SHOCKED WHEN I SAW HOW MUCH MONEY CAME FLOODING INTO MY PAYPAL ACCOUNT

That's right my PayPal account. It is now possible to achieve the same or even greater returns by listing emails that have their own PayPal accounts. The only things you will need are: An email address. A Business PayPal account with at least $6 deposited in it, and just 15 to 30 minutes of your time. This program takes just half an hour to set up. After that, there is absolutely no work whatsoever to do on your part. You have absolutely NOTHING to lose, and there is NO LIMIT to the amount of income you can generate from this one single business program.
Just follow the instructions exactly as set out below and then prepare yourself for a HUGE influx of cash over the next 30 days! Here's what you need to do to get started NOW. . .

REQUIREMENTS

1. An email address
2. A Premier or Business PayPal account

STEP 1:

Setting up your FREE PayPal Account It's extremely safe and very easy to set up a FREE PayPal account! Copy and paste this to the address bar

https://www.paypal.com (notice the secure "https" within the link). Be sure to sign up for a free PREMIER or BUSINESS account (and not just a PERSONAL account) otherwise you won't be able to receive credit card payments from other people.

STEP 2:

Sending PayPal money "It is an undeniable law of the universe that we must first give in order to receive." Now all you have to do is send $1.00 by way of PayPal to each of the six email addresses listed below. Make sure the subject of the payment says...

PLEASE PUT ME ON YOUR EMAIL LIST
(this keeps the program 100% legal...so please don't forget!)

Note: (If you do not see the full email address for the 6 members, just

hit reply to this email and they will show up.)

(Just in case you still haven't opened your PayPal account yet, use this link to open one in your name), https://www.paypal.com

1.) wilsoncrenshaw@msn.com
2.) prem_ks@hotmail.com
3.) corey_grayson@hotmail.com
4.) sueandbrian@execulink.com
5.) postachio@hotmail.com
6.) brooklynspy007@yahoo.com

STEP 3:
Adding Your Email Address
After you send your six $1.00 payments, it's your turn to add your email address to the list! Take the #1) email off the list that you see above, move the other
addresses up one (6 becomes 5 & 5 becomes 4, etc) then put YOUR email address (the one used in your Pay Pal account) as #6) on the list.

MAKE SURE THE EMAIL YOU SUPPLY IS EXACTLY AS IT APPEARS IN YOUR PAYPAL ACCOUNT.

STEP 4:

The Pure Joy of Receiving PayPal Money!
You are now ready to post your copy of this message, to at least 200 newsgroups, message boards, etc.

All you need is 200, but remember, the more you post, the more money you make - as well as everyone else on the list! In this situation your

job is to let as many people see this letter as possible. So they will make you and me rich!!!! You can even start posting the moment your email is confirmed. Payments will still appear in your PayPal account even while your bank account is being confirmed.
Remember stick to the game plan, be honest and don't get carried away and you'll make some cash! Good luck out there.

DIRECTIONS FOR HOW TO POST TO NEWSGROUPS

Step 1:

You do not need to re-type this entire letter to do your own posting. Simply put your cursor at the beginning of this letter and drag your Cursors to the bottom of this document, and select 'copy' from the edit

menu. This will copy the entire letter into the computer's memory.

Step 2:

Open a blank 'notepad' file and place your cursor at the top of the

blank page. From the 'edit' menu select 'paste'. This will paste a copy

of the letter into notepad so that you can add your name to the list.

Step 3:

Save your new notepad file as a .txt file. If you want to do your postings in different settings, you'll always have this file to go back to.

Step 4:

Use Netscape or Internet explorer and try searching for various newsgroups (on-line forums, message boards, chat sites, discussions, etc.)
Step 5:

Visit these message boards and post this article as a new message by highlighting the text of this letter and selecting paste from the edit menu. Fill in the Subject, this will be the header that everyone sees as they scroll through the list of postings in a particular group, click the post message button.
You're done with your first one!

Congratulations...THAT'S IT!

All you have to do is jump to different newsgroups and post away, after you get the hang of it, it will take about 30 seconds for each newsgroup!

REMEMBER, THE MORE NEWSGROUPS YOU POST IN, THE MORE MONEY YOU WILL MAKE!! BUT YOU HAVE TO POST A MINIMUM OF 200

That's it! You will begin receiving money from around the world within days! You may eventually want to rent a P.O.Box due to the large amount

of mail you will receive. If you wish to stay anonymous, you can invent

a name to use, as long as the postman will deliver it.

JUST MAKE SURE ALL THE ADDRESSES ARE CORRECT.

Now the WHY part:

Out of 200 postings, say I receive only 5 replies (a very low example).

So then I made $5.00 with my name at ..5 on the letter. Now, each of the 5 persons who just sent me $1.00 make the MINIMUM 200 postings, each with my name at ..5 and only 5 persons respond to each of the original 5, that is another $25.00 for me, now those 25 each make 200 MINIMUM posts with my name at ..4 and only 5 replies each, I will bring

in an additional $125.00! Now, those 125 persons turn around and post the MINIMUM 200 with my name at ..3 and only receive 5 replies each, I will make an additional $626.00! OK, now here is the fun part, each of those 625 persons post a MINIMUM 200 letters with my name at ..2 and they each only receive 5 replies, that just made me 3,125.00! Those 3,125 persons will all deliver this message to 200 newsgroups with my name at ..1 and if still ONLY 5 persons per 200 newsgroups react I will receive $15,625,00! With an original investment of only $5.00! AMAZING! When your name is no longer on the list, you just take the latest posting in the newsgroups, and send out another $5.00 to names on the list, putting your name at number 5 again. And start posting again.

>I don't see the point here.

Hi John,

Rather simple one given the stark contrast to claims made by fractalists.

What is the mathematical relationship between:
fractal form and drivepoint Z;
fractal form and resonance;
fractal form and performance?

I can answer those questions, can you? Well, perhaps not literally you, but how about any author you've read? No, they are silent on these topics too, except for the most specific and confined sliver of research that has then been grandiosely projected into the general field. Such is "promise," research inflation.

What is the total length of wire needed to construct a Koch Quadratic to resonate in the 40M band? What is the drivepoint Z of a 3rd iteration of a Sierpinski form at resonance? Which form provides better low angle launch characteristics, a Triangle Sweep monopole, or a Koch Triadic monopole? I can answer those questions with specifics.

What is distinctive about 16M of wire constructed in the form of a 2nd Order Sierpinski? Could you have forecast 80 MHz bandwidth below and including the 2M band from the formulaic expression? I know you couldn't.

For the 1st, 2nd, 3rd, and 4th iterations of a fractal form, can you express how much the progression of resonance shift will occur? Worse yet, can you relate the math of the iteration to ANY frequency? You would have to visit my work first to do that.

If after all these years of study, you cannot find these basic questions answered in the research, and they were all commonly derived for Marconi antennas; it follows that there is nothing distinctive about your dismissal:
>rather elementary
>(and physically large) wire structures and did not have to generally
>concern himself with design issues such as antenna gain/radiation pattern,
>efficiency, driving point impedance, size, weight, etc.
now being offered as a fractal boon to mankind. And yet Marconi and others DID quantify all these characteristics even if you diminish

that past era's need or care in marked contrast to their explicit role, that is center stage today.

Simply put, "research" it is not. What has been published is and has always been called "hi-grading." If this term is unfamiliar to you, it comes from the mining community where a prospector only works the best deposits and ignores the rest. The "researchers" are not describing any qualities of the generic fractal form, they have simply confined their studies to those that have been discovered to have interesting characteristics and have discarded the rest. They could have as easily been focused on Penrose tiles and made the same "discoveries" once they discarded those tiles that were performance busts. This does not elevate Penrose tiles to the status of "having promise."

These discoveries are still based on CHANCE not prediction. Fractals are the Three Card Monty of antenna research.

==========

A better way of studying and predicting what happens during a
lightning stroke is to consider conductors to be transmission lines
having R, L, C and G, and a velocity factor. The generator is a high
impedance, narrow, pulse of current.

Reflections from the ends can be considered. Very crude estimates of
system parameters are inevitable but much better than nothing.

Jim Kelley, AC6XG wrote:
"I think Farqaday stilll provides the best explanation."

Yes. Faraday showed d-c had nothing to do with wireless. It was the a-c motivating wireless electrical coupling.

An Englishman, Faraday, constructed a transformer in 1831. He used two isolateed coils of wire wound on the same spool. He connected a galvanometer across one coil. He noticed a brief deflection of the galvanometer each time he connected or disconnected a battery to the second coil.

Joseph Henry, a professor at Albany Academy in New York was independently making the same observations at the same time as Faraday. When Henry got news of Faraday`s discoveries, he made no effort to claim credit for his own work but often referred to Faraday`s discovery.

It was the change in the magnetic field which induced electricity without a direct connection, not the value of the steady magnetic field itself.

Same with antennas. A battery connected to an antenna sends no signal. A varying field is required to produce a signal in an antenna.

Hi Richard,

As much as the practical consequence is supported by this statement, it is not literally true.

The battery (which requires no attachment, but neither does it suffer one) does send a signal. It happens to be a static polar field. Any charge within the vicinity (and arguably that is out to the edge of the cosmos) will perceive its presence, OR its absence. Hence it contains at least binary information. If we know the polarity of the charge, then it contains at least quadratic information.

Within the dynamics and scope of life, there are many static charge signals that hinge upon these 2 bits of information. Now, given I used the terms dynamic and static in the same breath....

these are speculations that have been made by many without sufficient
testing. the holes in towers are generally much too large to act as a
reasonable faraday cage. nor is the change in inductance from being inside
the tower vs strapped to a leg likely to affect the surge voltages enough to
make a difference. (and it makes removal or replacement much harder!)
besides, even if being inside the tower somehow prevents voltage from being
induced on the cable, it has to exit the tower somewhere... and since the
insulation on any common cable can't withstand the possible hundreds to
thousands of kv potentials caused by lightning they are going to be
punctured anyway if not properly connected to the tower with appropriate
arresters. the same goes for running cables in conduit, if the end of the
couduit is at a high voltage from the lightning currents it will arc over to
the cables where they exit unless properly equalized.

Also, the world class lightning expert i used to work with just laughed at
the idea that a bend in a wire could cause lightning to not follow it. and
in all the work i did on their very detailed lightning simulation software
there was no consideration given for bends in the wires... and in all the
research into algorithms i remember no journal papers discussing bending of
wires as a form of lightning protection... and i'm sure that if it was a
good method it would be widely used since it is so easy to do.

Mathematically it means to take the derivitive, or evaluate the slope of a time varying quantity. Electronically it means the antenna acts as a high pass filter - effectively blocking DC and attenuating low frequency signals.

jk

Cecil Moore wrote:

> It means that steady-state DC is incapable of generating photons.

You forgot about the flashlight again, didn't ya Cecil. Photons are generated when the steady state DC source is applied to the light bulb inside. They are allowed to escape through the clear part in the front of the flashlight. :-)

By the way, my nephew just graduated from UCSD with a bachelors in Photonics Engineering. He told me that the photonics engineering discipline is virtually all applied wave mechanics.

Slight correction: it is the change in the magnetic flux that gives
induced EMF. You can get an induced current from a constant
magnetic field if the circuit loop moves in or out of the field,
changing the flux throught the loop.

Well, Richard I'll certainly be looking forward to your next IEEE paper on the subject where you can set the rest of the antenna design world straight since you clearly have this expertise ;-) I'll state up front that I have definitely not published any fractal-design antenna papers. I choose to keep an open mind on the subject whether or not "hi-grading" takes place or not. Engineering has never been an exact science and quite often you simply cannot easily write an equation for an electrical property as a function of say, frequency. When it comes to antennas things get messy in hurry when you go beyond basic geometries. If you think not, try perusing the pages of "Antenna Theory", Vols. I and II by Collin and Zucker (published by McGraw-Hill)

Show me a fractal (or some other type) antenna and some repeatable, measured data. If you have modelled it with an antenna modelling program (e.g. the Numerical Electromagnetics Code (NEC)) and the modelled and measured data compare favorably, that's good. We can then decide if we have a candidate fractal antenna for inclusion into, for example, a cell phone, gps receiver or RFID tag that provides the sought-after antenna characteristics for that application. I should also state that my comments are in consideration of all applications requiring antennas in small spaces, not exclusively those of interest to the amateur radio community. Sincerely,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

Hi Reggie,

Each are 16 meters tall:

2nd Order Koch Quadratic monopole at 26 MHz exhibits:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Height/2nd%20order/16%20meter%20tall%20Quadratic%20Koch%202nd%20order%2026%20MHz%20Elevation%20Lobes.gif

2nd Order MB Curve monopole at 25 MHz exhibits:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Height/2nd%20order/16%20meter%20tall%20Quadratic%20Koch%202nd%20order%2026%20MHz%20Elevation%20Lobes.gif

2nd Order Sierpinski monopole at 26 MHz exhibits:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Height/2nd%20order/16%20meter%20Sierpinski%202nd%20order%2026%20MHz%20Elevation%20Lobes.gif

Simply (sic) scale to the 160M band (230 meters tall, more or less).

I could offer eight more, but then you don't really qualify what you
mean by the subjective term "better." They are all "better" on paper,
which I suppose means they show promise. ;-)

See John, Phil, Dave, Jim, Harry, David, Owen, Fred, Rod? How many
papers, articles, links, or claims gushed over the airwaves offer as
much succinct response as above? One design is asked for and I can
offer 11.

Hi John,

That was done some 4 years ago, several times over by Steve Best, V9SRB. If you wish to commemorate the fractal's demise, then visit the scene of that massacre.

>Show me a fractal (or some other type) antenna and some repeatable,
>measured data. If you have modelled it with an antenna modelling program
>(e.g. the Numerical Electromagnetics Code (NEC)) and the modelled and

I've done just this for Reggie in a separate post. It barely represents 1% of my work.

>We can then decide if we
>have a candidate fractal antenna for inclusion into, for example, a cell
>phone, gps receiver or RFID tag that provides the sought-after antenna
>characteristics for that application.

Those same papers also invalidated these presumed attributes, and they were done according to first principles, not the chance of discovery.

The archives are rich in this material's coverage. These same postings also offer the bane of fractal implementation - excessive convolution.

As is so painfully obvious, if fractals were a good idea, we would be using them now.

I wonder why they don't rebuild New Orleans the way they built Venice,
Italy. Venice was built by people who were trying to get away from
Attila the Hun. Attila wanted farmland, so the nomads of that area
fled and settled in what was a swamp, and they built a city on a
swamp.

(Of course, the first one sank into the swamp, so they built a second
one. THAT one sank into the swamp, so they built a third one. THAT one
burned down, fell over, and then sank into the swamp...but the fourth
one stayed up!)

Seriously, though, New Orleans as a city of canals has a certain
romantic flair to it.

A fractal antenna is a space-saving device and cannot
"work better than" full sized antennas. A comparison
of fractal antennas and small loops would be much more
interesting.

Reg, G4FGQ wrote:
"A better way of studying and predicting what happens during a lightning strike is to consider conductors to be transmission lines having R, L, C, and G, and a velocity factor."

Could be. I reiterate that experience shows lightning taking the easy accessible path.

If you don`t want lightning traveling on the outside of your coax, hide the coax from the lightning, increase the impedance of the coax exterior, and give the lightning a lower impedance alternate path.

A conductor can offer inductive reactance in addition to its resistance. Put some twists and turns in the coax. A coil`s inductance is proportional to the square of its number of turns.

The inductance of a straight wire is directly proportional to its length and varies inversely with its diameter. Terman says connecting wire inductance can be minimized by making the diameter large (1955 edition, page 13).

If you want to know the inductance of anything, a good place to start looking is Terman`s 1943 "Radio Engineers` Handbook". Someone asked the impedance of a link couplling loop a few days ago. You can find its inductance using the handbook and if you know the frequency the calculation is easy.

In my previous posting, I suggested placing the coax in close proximity with the much larger diameter radio tower. I reasoned that the larger tower has proportionally less inductance and would likely take a lion`s share of the lightning current.

The coax would be better off inside the tower where it is somewhat screened from strikes.

Working decades with radio towers and cables, I`ve seen this protection work.

Reg, I just modeled a 160m dipole (246 ft) Vs a 150 ft.
overall length fractal dipole, both at 100 ft. The gain
of the full sized dipole was 5.54 dBi at 45 deg TOA and
the gain of the fractal dipole was 5.24 dBi at 45 deg TOA.
You think you could tell the difference on the air?

Looking from above, it looks like this:

```
-----+ +-----x-----+ +-----
| | | |
+----+ +-----+
```

Each section is 25 ft. It's just a way of folding an
antenna that meets the fractal specifications.

Just in case someone doesn't understand your silly humor, Jim, here's
the original posting:

"It is said that a transmitted UWB pulse should not have any DC because
of the transmitting antenna:"

Antennas emit coherent photons. As far as I know, there's no such thing
as a DC coherent photon, but if I'm wrong, please enlighten us. It's obvious
that I was talking about coherent photons but just for you I will repeat with
the context included this time:

Steady-state DC is incapable of generating coherent photons from an antenna.

Iok so i am confused on a few things

the photo part

so regardless of weither or not there is or isn't ac or dc , when i xmit (ham or other freq's) are photons being generated??

where would they be?? nearfield? around the antenna?

how would i measure the presence/qty of such??

the other thing i got fuzzy on

static polar field as Mr. clark mentions so why does the battery produce it /how?? are you referring to the fact that is has 'mass' and therefore.... or did i miss the obvious

thanks

I have a remote tuner in my garage, about 100 feet from my shack. The fluorescent lights flicker in the garage when I transmit with the amplifier on. I suspect this means there are high voltages in the garage. It still works. I us the metal interior of the garage for a ground. The steel sheets that form the interior of the garage are wired together.

My Flashlight does it every time. Maybe you need new batteries.

What you DON'T say is what you are using for an antenna for those
photons. It would be ridiculous to use a 20M dipole. Maybe you don't
have the right antenna.

Cecil,

Have you ever heard of a laser diode? You may well use one every day.
Billions of them are made every year for CD players and many other gadgets.

DC goes in; coherent photons come out.

This item is actually a transducer in which electromagnetic fields in a
conductor are converted to electromagnetic fields in space.

Hmmmm, sounds a lot like the function of an antenna.

> that, and besides, the Netherlands doesn't have to worry about
> hurricanes either.

The levees are dikes, aren't they?

There are some important other differences.

It's my understanding that the Dutch built their dikes and filled
in/pumped out the polders as a way of getting more farmland without
fighting wars with their neighbors, and as a way of *reducing* storm
damage. They don't build cities on below-sea-level land. And the way
they deal with the reclaimed land results in it slowly but surely

rising, not sinking.

But they don't put cities there.

--

There's a bigger problem even than Katrina behind all this...

Modern technology has made almost anything possible from a theoretical point of view. NO could be rebuilt with levees and pumps capable of withstanding a Cat 5 storm, for example.

But the problem is that such solutions, while technically possible, are often prohibitively expensive, particularly on a large scale. Not just to build, but to maintain. Who is going to pay the taxes so that a rebuilt NO can be kept dry?

Or to put it another way - *why* should NO be built in such a highrisk location when there are so many better alternatives?

Just because something can be done doesn't mean it should be done.

I wonder if Shrub ever played SimCity?

Some of the lower forms of American Christianity try to separate faith
and works. That allows them salvation without substance, the lazy man's
path to life without end.
My last two sentences are statements of truth, not a logical
progression. Each has to be taken alone, by itself. (A religious
fundamentalist insisting on logical consistency constitutes a
pretty good joke.) Let me repeat: Those who do no good have no
faith. Next time you and your friends are sitting around speaking
in tongues, you should discuss this. Maybe, if you all think real
hard, together, you can puzzle out what it means.

Don't listen to these guys. They're changing the subject by changing the scale of the argument in order
to digladiate with one another. The truth is, that if an antenna really differentiates a signal so that what it radiates is based on the rate of change of the original signal, then the DC part of the original signal won't contribute to the radiation because the rate of change of a constant(the DC part)is zero. It isn't any more complicated than that.

well,
I am of the old school on this one myself: try it out, measure it and then duplicate the results (scientific method). personally, I'd like to get some of the math down first, and then get some building ideas and see what can be made to work for the average home user/ham...

I've built many an antenna since before I became a ham. There is walys something new to be learned from the building (such as math, construction techniques and the like).

I agree with what Richard Clarke says on this, any marketing hype is just that: snake oil salesmanship. I want to see real numbers and real results before I believe what someones marketing dept. printed up.

Hi Eric,

Yes, but the purpose of a newsgroup is to enlarge the general
understanding of a topic.

As for your topic of HDTV signals, the simple answer is one of the
oldest fractals (which is one of those claim grabs where the bastard
technology adopts its own grandparents for legitimacy's sake alone).

Try the Log Periodic Dipole Array. It is certainly wide band, but I'm
not so sure this equates to phase distortion free - if that is a
problem. I cannot say the problem interests me because I'm of the
opinion that HDTV will be serving HD crap. I long ago gave up on
cable because I was no more interested in 200 channels of crap than a
dozen or so over the air. Netflix is cheaper.

As for wide band fractals:

Bandwidth goes contrary to small size. Fractals boast of being small.
Widebandedness does not come with small, even if it does come with
being fractal. The design alluded to in another posting with this
kind of wide bandwidth:
http://www.qsl.net/kb7qhc/antenna/fractal/Constant%20Fractal/2nd%20Order/Sierpinski%2016M%20wire%202nd%20order%20377%20Ohm%20SWR%20Special.gif
covers EVERY VHF TV channel with below 2:1 SWR.

This design comes with a huge price. It consumes 64 meters of wire!

If you are looking for gain, you are looking at size again. If not in
the overall spread, then in the overall outline. Fractals only boast
of size (when they are smaller) because they can be tailored for a
match. TV antennas, for years, have long solved matching problems.

If you are looking for radiation lobe characteristics, fractals are
not notably intuitive models of symmetry. In fact they are as
perverted in their kinky patterns as they are with their kinky wire.

You could build an array from these loops:
http://www.qsl.net/kb7qhc/antenna/fractal/Square%20Gasket/index.htm
which performs just as well or better than its larger, conventional

design, but you clearly state above:
>would work with a minimum of complexity...
which negates nearly the entire topic.

If none of this dissuades you, write me offline and we will keep it there. Certainly there is a limit to the interest online, and it usually dies at about the 5 or 6th post in the thread as it did here. The only thing that kept it alive in times past was the carnival atmosphere and hucksterism.

Hi Eric,

One of the Amazing Randy's most compelling points made is that experts
are the easiest marks of the con-man, and make great suckers for
complex scams.

It remains painfully obvious to the non-expert that such remarkable
qualities would naturally surface quickly as the mainstream choice.

It has not happened for very many, good reasons. If "we" don't know
how to use them, and you cannot find anyone who can, it stands to
reason that only an expert could make sense of this.

Really, fractals make kewel patterns, and they should be more useful
than spirographings for tots, but as for the rest of it there is a
useful saying that aptly fits:
A solution in search of a problem.

What pisses me off about your posts is this almost deliberate attempt to obfuscate by equivocating, word playing and substituting terms which are incompatible. You keep doing it in almost every post and it gets tired fast. Like, for instance, in the example above: "plenty of evidence but no proof" is meaningless drivel. Of all the scientific disciplines, only mathematics deals with proof. Others, physics included, deal with evidence which is derived from a direct or indirect observation of certain phenomena and is the basis for a theory, such as the gravitational theory, for example.
Therefore, to say that there is "no proof" for gravity is gibberish, even in the solipsist sense.

73 .... WA7AA

P.S. I am dying to hear some "evidence" of what you call "G-d". I am sure the Nobel committee would be interested as well.

I can answer that one..

One of the thieves was reportedly cussing and making fun, challenging
Him to prove He was better than they were. The "good thief" told the
"bad thief" to be quiet, because while they deserved what they got, He
had done nothing wrong. Then the "good thief" asked to be remembered.

It may not seem like much of a "good work", but it was all the good
thief could do. His faith came very near the end of his life.
But what about those whose faith comes much earlier in life?

The Netherlands version of dikes are to levees as a FT-9000 is to a
Rock Mite. I watched a documentary on the things once, and they are
quite a feat of engineering. They are considered one of the seven
woncers of the modern world.

RH> A conductor can offer inductive reactance in addition to its
RH> resistance. Put some twists and turns in the coax. A coil`s inductance
RH> is proportional to the square of its number of turns.

I think you are missing one thing that seems to be much too obvious.
Air conducts 10 times better than the plastic insulation in the coax
and the lightning will simply jump over the twists and turns, without
the slightest effort.

What you really want to do is to give lightning an alternate path that
conducts better than the air, so that your coax is ignored.

However, I think you are right in giving the coax path more inductance
because the lightning leader is a high frequency phenomenon and it is
the leader that initiates the path for the lightning strike.

Very true on the macro scale but even a DC potential becomes
discontinuous at a microscopic level. Remember that there is a
distance between atoms, electrons, molecules and are not continuous.
How is it done except if not by photons, virtual or otherwise, whether
the context is AC or DC?

Cecil, an infinitely long antenna is simply an impedance transformation
between different mediums. i.e. wire to free space.

Say we point a yagi cut for 900MHz or 2.4GHz at the tower and instead
of using a coax to connect to the cellphone we use a balun to match a
small vertical directly connected to it. Then use the cellphone in
proximity to the yagi/balun/vertical combined antenna. If the yagi has
say +12dB gain then won't the vertical reradiate and recieve with that
added gain or is this one of those perpetual motion impossible gizmos?

Fe> can be? Any advice is more than I currently have. Thanks...

The radio's built-in whip antenna only works for the FM tuner. The AM
antenna is a ferrite loopstick directly mounted on the circuit board.
There is no connection between the two antennas.

What you might try is to make a coupling loop with some turns of wire
(10+). Connect the ends of this to the coax, center and braid. Then
place the loop vertically near the radio oriented so that the AM
loopstick points at the center of the loop (taped to side of case).
You might improve it by adding a variable trimmer cap in series with
the coax or in parallel across the loop to tune sensitivity.

Other than this try leaving the radio outside and extend the speaker
wire instead.

DC applied to an antenna no doubt creates virtual photons.
My statements should be considered to exclude such virtual
photons. They are meant to include only detectable photons
coherent with the frequency of the driving signal capable
of propagation through free space which are emitted by the
acceleration/deceleration of free electrons in a copper
wire antenna. (Contexts nowadays are sure complicated.)

Hi Harry,

They are all pretty much based on the biconical dipole. The most
familiar example is half of it, found at Radio Shack, as the Discone:
http://www.qsl.net/kb7qhc/antenna/Discone/discone.htm

If you have any working knowledge of the Smith Chart, then you may
notice by the degree of the cone apex angle, that the widebandedness
is a function of the flare of the skirt.

The primitive form would be a simple, thick wire, which has an
equivalent known as the Cage:
http://home.comcast.net/~kb7qhc/antennas/verticals/Cage/cage.htm

As the wire gets thicker, its resonance falls and its bandwidth
increases.

the 'leader' is usually referring to the charge that is coming down from the cloud and attracting the charge on the ground to it. this process is actually relatively slow, as it the growth of the streamers up from the ground. just note how long you have from when your hair starts standing up to dive into a ditch, that is hardly a high frequency event.

To make an antenna wideband, you have to decrease the Q, Making the antenna "fatter" is one of the approaches.

For example a standard 12 gauge wire dipole at 3.8 MHz has a bandwidth of about 120 KHz (defined as the 2:1 SWR points) . Making a cage 12" in diameter with 6 wires and depending on height you can cover almost 300 KHz. Use two dipoles with the ends separated by 15 feet and you can cover almost all of the band.

What specific frequencies are you trying to cover? How much SWR can you stand, and what is the link budget?

> wide-band antennas. Am I right?

==========

Harry, Yes, you are right.

Simply suppress resonant tendencies. Make antenna Q = 1 such that the feedpoint impedance is always a pure resistance at all working frequencies.

The most simple, most wide-band antenna is just a wire terminated in its characteristic impedance Zo. Simpicity Rules.

Unfortuately and inevitably, at least 50% of the Tx power is dissipated in the termination. But if power is inexpensive, who cares?

There are compromises between bandwidth, directional properties, service area, power-efficiency and physical construction. But there is always more lost on the roundabouts than is gained on the swings.

At HF, when it comes to compromises, you can't beat a 1/2-wave horizontal dipole or a 1/4-wave vertical.

I trust the above somewhat vague information will be of interest. Perhaps further details can be provided by people having practical experience of particular cases such as Fractal and E-H antennas.

Reg, G4FGQ.

That's the basic reason one will not see many fractal
antennas used for HF antennas and practicality was
not the context. But on a higher frequency, with self
supporting material, and bending it down instead of out,
it makes more sense, e.g. 6m, ~5 ft. long instead of ~9
ft. long. Consider the turning radius for a 6m fractal
beam Vs a full-sized one.

The standard of discussion on Fractals on this newsgroup certainly
relegates the Fractal antenna to the place it deserves.

But it has not yet descended to the level of the E-H.

Get yourselves organised, Try harder!

Reg.

It's so simple to derive the value of 73 ohms.
Just divide 146 by 2.
Or multiply 36.5 by 2.
There are other ways of doing it.

BPL sound so nice until you get to the pollution aspect (RFI).

As I told the Atlanta based Earthlink CEO, hams will be a nuisance until one of us ingresses (not really as its not inside a cable) and blocks out the entire system. Then the stuff will really hit the fan. A national article stating that ham radio op KX3XXX imterfered with the city of YYYYY's cable system
would do it,

Rod,

Several years ago I tried a 14AVQ vert next to the house with a big
jumper to the tin roof. Boy was that a mistake! It did not work at
all. I gave up on the vert and installed a tower and beam.

FYI, the best improvement ever made to the beam was when we replaced
the tin roof with normal singles. It was like getting a new antenna too.

Good luck with the tin roof. BTW, it did work pretty good with a mag
mount VHF/UHF antenna. HiHi

Has anyone had any experience with the KenPro 050 thrust bearing? I am thinking of using one on a 40 lb monobander, with a K of about 700, three feet above the roator, on a 2" mast, with the antenna extending four feet above the bearing. Since the antenna is lights, I really don't need the bearing to support the vertical weight of the antenna and mast.

They are about a quarter of the price of a TB-2.

Just modeled a quickie using EZNEC. The fractal beam has two elements with 6 ft. tip to tip spaced two feet apart. Each element looks like this typical fractal with the reflector slightly longer than the driven element:

```
1' 1' 1' 1' 1' 1'
----+ +----x----+ +----
1'| | | |
+----+ +----+
```

Each line is one foot long and the feedpoint is at 40 ft. On 53 MHz, this two element fractal beam has a gain of 12.6 dBi at 7 deg. TOA with a F/B ratio of 18.5 dB. Looks pretty functional to me.

Years ago in Europe I installed a phased quarter wave vertical array
for 20 meters on an appartment house complex metal roof pointed to
the states. It was very close to 50 ohms at the feed point. The
antenna worked great. The metal was actually under about an inch of
roofing compound, but was well grounded.

Surely, it is worth a try with the Butternut.

Ham radio is gradually on its way out. The authorities will not allow it to interfere with other forms of radio transmission.

In any case, insofar as the authorities are concerned, ham radio is an insecure means of communication. It is difficult to intercept, monitor and control the traffic which passes over it.

Even radio broadcasting is being pushed onto the Internet. It will be noticed the BBC international broadcasts are not now beamed to the USA but are advertised as being readily available to USA listeners via the Internet. The Internet is easily intercepted, monitored and controlled by the authorities. Whoever THEY may be.

They who own and control the means of communication, including that via satellites, will rule the Earth.

Actually, something that we call gravity undeniably exists. While our understanding of it is incomplete, there is no doubt that it exists. It is there, we see what happens if we drop someting in an area where "gravity" is strong, and in areas where it is virtually nonexistant.

The "proof" if you will, is in the explanation and understanding of what we call gravity, not it's existance.

Now God on the other hand, gives no real evidence at all for existence. Miracles are manifestations of chance, and many things that were once attributed to divine intervention have found ready explanations after we learn more about the universe.

So the statement was incorrect in the first place.

Hi Mike,

As it so happens (and if properly choked) your OCF dipole is probably
superior to many fractals on their own terms of being multi resonant.
And regrettably yes, that would then make it fractal by appropriation
and claim by the fractal community (something of the Borg mentality
there).

Cec, You know as well as I do, take-off angles are meaningless regarding who might, by some remote coincidence, be at a distance and in a direction to receive.

Front-to-back ratios are equally meaningless. Nobody takes any notice of them when a slight change in frequency, a minute change in antenna dimensions, or the wind direction acting on an antenna is taken into account.

Hardly parameters which can sensibly be used to compare one antenna with another.

I mention this here only for the benefit of novices who may be misled by your comments. ;o)

Reg.

Michael Coslo wrote:
> Isn't that straining the definition of fractal a bit?

Nope, that's a well known fractal pattern. It even has
a name within the fractal community but it slips my
mind at the moment. It might be a Koch or Hilbert
pattern, I forget. I haven't looked at this stuff in
a coon's age.

```
----+ +----x
| |
+----+
```

That's a first level iteration pattern. The second level
iteration would replace each of those one foot lines with
the same overall pattern as above - something like:

```
----+ +----+ +----+ +----x
| | | | | |
+----+ +----+ +----+ +----+
| |
+----+ +----+
| |
+----+ +----+
| |
+----+
```

There were five wires in the first level iteration. Each of
those five wires is replaced with the original basic pattern.
Do you see five repeats of the original pattern in the above?

Ian Jackson wrote:
"What is the impedance at the centre of an infinitely long dipole in free space?

It is the antenna`s Zo. This depends on the size of the conductor used to make the dipoole.

Arnold B. Bailey has already worked all this out and presents it in his 1950 edition from Rider`s of "TV and Other Receiving Antennas".

Like the Zo of a transmission line, antenna Zo has nothing to do with reflections and terminations. When you first apply power, energy must flow into the antenna at some definite voltage to current ratio. This is the surge impedance or Zo. If the antenna or line is uniform and infinitely long, the energy sent away is never heard from again. Zo is the only impedance anywhere.

Page 345 gives the surge impedance in ohms for a balanced antenna as:

Zo = 276 log 1/P

P is the circumference of the antenna rod, or periphery, expressed as a fraction of the free-space wavelength (see page 342) This may sound goofy but Bailey has his reasons.

Bailey`s graph on page 345 gives dipole impedances from 70 ohms to 680 ohms for rod peripheries from 1 wavelength down to 0.00001 wavelength

If you have no reflections or standing waves, the impedance you calculate should be the Zo.

Best regards, Richard Harrison, KB5WZI

Is the graph impedance looking into 1/2 of the dipole?
276 log 1/0.00001 = 1380 ohms, just about double the 680 ohm value.

The impedance looking into the feedpoint of an infinite dipole is
TWICE Zo.

Zo + Zo = 2*Zo.

The formula for Zo doesn't seem right. When the circumference of the
antenna rod is one wavelength, Zo = 0.

And when the circumference is greater than one wavelength, Zo becomes
negative.

For an 18 gauge wire, at a frequency of 183 GHz, something funny
happens.

Reg.

How much of Death Valley is not below sea level?

From http://hypertextbook.com/facts/2000/MichaelLevin.shtml

The hottest temperature on Earth ever recorded most likely occurred in
Death Valley, California during 43 consecutive days between July 6 and
August 17, 1917. During those days, the temperature was over 48
degrees Celsius (120 degrees Fahrenheit). The national weather service
recorded 56.7 ï¿½C (134 ï¿½F). The date reported there was July 10, 1913.

The elevation in the lowest point is 86 meters below sea level.

Anyone recently seen an old (40s or so) copy of the Stephen
Foster Songbook? Nearly every facing page with a sketch of happy,
carefree, little darkies, havin' a wunnerful time, singin', dancin'
and playin' their fiddles.

Showing something in its historical context is not censorship.
Would you set up an exhibit of historical KKK robes on your front
porch without an explanation?

We're trying to embarrass your delete key into admitting it's
impotent.

Does anyone know where I could find a source of 3/8 to SO-239 mount (SO-239 female socket on one side and 3/8 threaded stud on other side connected to centre pin).

Prefer Australian source if you know of one otherwise anywhere I can purchase in bulk at wholesale.

Thanks in advance

Regards

David

Mommy and Daddy have been dead since 95 and 61, respectively.

If you think you're important enough that I should leap to the
keyboard daily, you're sadly mistaken. I may only look in once a week.
Live with it.

So, you're not only full of shit on both counts, you're also
wrong.

And just how hollow is your life that you have to track my
posting delays? Get a hobby.

>fundamentalist insisting on logical consistency constitutes a
>pretty good joke.) Let me repeat: Those who do no good have no
>faith.

Repitition does not include leaving off the first half of the
line you wrote. In a humorous logic treatise, your statement would be
named "The Proof from Blatant Assertion".
